coop*Co-operative Trial in Analytical Chemistry*

---

**Description**

Seven specimens were sent to 6 laboratories in 3 separate batches and each analysed for Analyte. Each analysis was duplicated.

**Usage**

coop

**Format**

This data frame contains the following columns:

Lab Laboratory, L1, L2, ..., L6.

Spc Specimen, S1, S2, ..., S7.

Bat Batch, B1, B2, B3 (nested within Spc/Lab),

Conc Concentration of Analyte in *g/kg*.

**Source**

Analytical Methods Committee (1987) Recommendations for the conduct and interpretation of co-operative trials, *The Analyst* **112**, 679–686.

corresp*Simple Correspondence Analysis*

---

**Description**

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

**Usage**

```
corresp(x, ...)

## S3 method for class 'matrix'
corresp(x, nf = 1, ...)

## S3 method for class 'factor'
corresp(x, y, ...)

## S3 method for class 'data.frame'
corresp(x, ...)

## S3 method for class 'xtabs'
corresp(x, ...)

## S3 method for class 'formula'
corresp(formula, data, ...)
```

**Arguments**

<code>x, formula</code>	The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class " <code>xtabs</code> " and formulae of the form $\sim F1 + F2$ , where $F1$ and $F2$ are factors.
<code>nf</code>	The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.
<code>y</code>	a second factor for a cross-classification.
<code>data</code>	a data frame against which to preferentially resolve variables in the formula.
<code>...</code>	If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.

**Details**

See Venables & Ripley (2002). The `plot` method produces a graphical representation of the table if `nf=1`, with the *areas* of circles representing the numbers of points. If `nf` is two or more the `biplot` method is called, which plots the second and third columns of the matrices  $A = D_r^{-1/2} U L$  and  $B = D_c^{-1/2} V L$  where the singular value decomposition is  $U L V$ . Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does *not* have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

**Value**

An list object of class "`correspondence`" for which `print`, `plot` and `biplot` methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

biplot(corresp(caith, nf = 2))
```

---

cov.rob

*Resistant Estimation of Multivariate Location and Scatter*

---

**Description**

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the `good` part of the data. `cov.mve` and `cov.mcd` are compatibility wrappers.

**Usage**

```
cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
        method = c("mve", "mcd", "classical"),
        nsamp = "best", seed)

cov.mve(...)
cov.mcd(...)
```

**Arguments**

<code>x</code>	a matrix or data frame.
<code>cor</code>	should the returned result include a correlation matrix?
<code>quantile.used</code>	the minimum number of the data points regarded as good points.
<code>method</code>	the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using <code>cov.mve</code> or <code>cov.mcd</code> forces <code>mve</code> or <code>mcd</code> respectively.
<code>nsamp</code>	the number of samples or "best" or "exact" or "sample". If "sample" the number chosen is $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted however many samples are needed.
<code>seed</code>	the seed to be used for random sampling: see <a href="#">RNGkind</a> . The current value of <code>.Random.seed</code> will be preserved if it is set.
<code>...</code>	arguments to <code>cov.rob</code> other than <code>method</code> .

## Details

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be `good`. The final estimates are the mean and rescaled covariance of the `good` points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an *ad hoc* finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of `p` of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

## Value

A list with components

<code>center</code>	the final estimate of location.
<code>cov</code>	the final estimate of scatter.
<code>cor</code>	(only is <code>cor = TRUE</code> ) the estimate of the correlation matrix.
<code>sing</code>	message giving number of singular samples out of total
<code>crit</code>	the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
<code>best</code>	the subset used. For MVE the best sample, for MCD the best set of size <code>quantile.used</code> .
<code>n.obs</code>	total number of observations.

cov.trob

*Covariance Estimation for Multivariate t Distribution***Description**

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

**Usage**

```
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
         maxit = 25, tol = 0.01)
```

**Arguments**

<code>x</code>	data matrix. Missing values (NAs) are not allowed.
<code>wt</code>	A vector of weights for each case: these are treated as if the case <code>i</code> actually occurred <code>wt[i]</code> times.
<code>cor</code>	Flag to choose between returning the correlation ( <code>cor = TRUE</code> ) or covariance ( <code>cor = FALSE</code> ) matrix.
<code>center</code>	a logical value or a numeric vector providing the location about which the covariance is to be taken. If <code>center = FALSE</code> , no centering is done; if <code>center = TRUE</code> the MLE of the location vector is used.
<code>nu</code>	'degrees of freedom' for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
<code>maxit</code>	Maximum number of iterations in fitting.
<code>tol</code>	Convergence tolerance for fitting.

**Value**

A list with the following components

<code>cov</code>	the fitted covariance matrix.
<code>center</code>	the estimated or specified location vector.
<code>wt</code>	the specified weights: only returned if the <code>wt</code> argument was given.
<code>n.obs</code>	the number of cases used in the fitting.
<code>cor</code>	the fitted correlation matrix: only returned if <code>cor = TRUE</code> .
<code>call</code>	The matched call.
<code>iter</code>	The number of iterations used.

---

denumerate

---

*Transform an Allowable Formula for 'loglm' into one for 'terms'*

---

## Description

[loglm](#) allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that [terms](#) can process.

## Usage

```
denumerate(x)
```

## Arguments

`x` A formula conforming to the conventions of [loglm](#), that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

## Details

The model fitting function [loglm](#) fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by [terms](#), which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely `n` is replaced by `.vn`. This allows [terms](#) to parse the formula in the usual way.

## Value

A linear model formula like that presented, except that where dimension numbers, say `n`, have been used to specify fixed margins these are replaced by names of the form `.vn` which may be processed by [terms](#).

## See Also

dose.p

---

*Predict Doses for Binomial Assay model*

---

**Description**

Calibrate binomial assays, generalizing the calculation of LD50.

**Usage**

```
dose.p(obj, cf = 1:2, p = 0.5)
```

**Arguments**

obj	A fitted model object of class inheriting from "glm".
cf	The terms in the coefficient vector giving the intercept and coefficient of (log-)dose
p	Probabilities at which to predict the dose needed.

**Value**

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer.

**Examples**

```
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)

dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)
dose.p(update(budworm.lg0, family = binomial(link=probit)),
        cf = c(1,3), p = 1:3/4)

---

dropterm

---

*Try All One-Term Deletions from a Model*

---

## Description

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

## Usage

```
dropterm (object, ...)

## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
         k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, ...)

## S3 method for class 'glm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, trace = FALSE, ...)
```

## Arguments

<code>object</code>	A object fitted by some model-fitting function.
<code>scope</code>	a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
<code>scale</code>	used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>aov</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.
<code>test</code>	should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>aov</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test ( <code>lm</code> models with known scale) or a likelihood-ratio test depending on the method.
<code>k</code>	the multiple of the number of degrees of freedom used for the penalty. Only <code>k = 2</code> gives the genuine AIC: <code>k = log(n)</code> is sometimes referred to as BIC or SBC.

sorted	should the results be sorted on the value of AIC?
trace	if TRUE additional information may be given on the fits as they are tried.
...	arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (`lm` models with specified scale) the constant is taken to be that used in Mallows'  $C_p$  statistic and the results are labelled accordingly.

Value

A table of class `"anova"` containing at least columns for the change in degrees of freedom and AIC (or  $C_p$ ) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

```

---

 epil

---

*Seizure Counts for Epileptics*

---

**Description**

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject's age is the only covariate.

**Usage**

epil

## Format

This data frame has 236 rows and the following 9 columns:

`y` the count for the 2-week period.  
`trt` treatment, "placebo" or "progabide".  
`base` the counts in the baseline 8-week period.  
`age` subject's age, in years.  
`V4` 0/1 indicator variable of period 4.  
`subject` subject number, 1 to 59.  
`period` period, 1 to 4.  
`lbase` log-counts for the baseline period, centred to have zero mean.  
`lage` log-ages, centred to have zero mean.

## Source

```

---

eqsplot

---

*Plots with Geometrically Equal Scales*

---

**Description**

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

**Usage**

```
eqsplot(x, y, ratio = 1, tol = 0.04, uin, ...)
```

**Arguments**

<code>x</code>	vector of x values, or a 2-column matrix, or a list with components <code>x</code> and <code>y</code>
<code>y</code>	vector of y values
<code>ratio</code>	desired ratio of units on the axes. Units on the y axis are drawn at <code>ratio</code> times the size of units on the x axis. Ignored if <code>uin</code> is specified and of length 2.
<code>tol</code>	proportion of white space at the margins of plot
<code>uin</code>	desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
<code>...</code>	further arguments for <code>plot</code> and graphical parameters. Note that <code>par(xaxs="i", yaxs="i")</code> is enforced, and <code>xlim</code> and <code>ylim</code> will be adjusted accordingly.

**Details**

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by `ratio`. Finally both are stretched by `1 + tol` to move points away from the axes, and the points plotted.

**Value**

invisibly, the values of `uin` used for the plot.

**Side Effects**

performs the plot.

**Note**

Arguments `ratio` and `uin` were suggested by Bill Dunlap.

farms.mca <- mca(farms, abbrev = TRUE) # Use levels as names
eqscplot(farms.mca$cs, type = "n")
text(farms.mca$rs, cex = 0.7)
text(farms.mca$cs, labels = dimnames(farms.mca$cs)[[1]], cex = 0.7)
```

fgl

*Measurements of Forensic Glass Fragments***Description**

The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

**Usage**

```
fgl
```

**Format**

This data frame contains the following columns:

RI refractive index; more precisely the refractive index is 1.518xxxx.

The next 8 measurements are percentages by weight of oxides.

Na sodium.

Mg manganese.

Al aluminium.

Si silicon.

K potassium.

Ca calcium.

Ba barium.

Fe iron.

`type` The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (`WinF`: 70), window non-float glass (`WinNF`: 76), vehicle window glass (`Veh`: 17), containers (`Con`: 13), tableware (`Tabl`: 9) and vehicle headlamps (`Head`: 29).

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

fitdistr

*Maximum-likelihood Fitting of Univariate Distributions***Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

```
fitdistr(x, densfun, start, ...)
```

## Arguments

<code>x</code>	A numeric vector of length at least one containing only <a href="#">finite</a> values.
<code>densfun</code>	Either a character string or a function returning a density evaluated at its first argument. Distributions "beta", "cauchy", "chi-squared", "exponential", "f", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.
<code>start</code>	A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).
<code>...</code>	Additional parameters, either for <code>densfun</code> or for <code>optim</code> . In particular, it can be used to specify bounds via <code>lower</code> or <code>upper</code> or both. If arguments of <code>densfun</code> (or the density function corresponding to a character-string specification) are included they will be held fixed.

## Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and `start` should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using [optim](#). The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named `lower` or `upper` are supplied (when `L-BFGS-B` is used) or `method` is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location `m` and scale `s`.

For the following named distributions, reasonable starting values will be computed if `start` is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by `mu` and `size`), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are [print](#), [coef](#), [vcov](#) and [logLik](#) methods for class "fitdistr".

## Value

An object of class "fitdistr", a list with four components,

<code>estimate</code>	the parameter estimates,
<code>sd</code>	the estimated standard errors,
<code>vcov</code>	the estimated variance-covariance matrix, and
<code>loglik</code>	the log-likelihood.

## Note

Numerical optimization cannot work miracles: please note the comments in [optim](#) on scaling data. If the fitted parameters are far away from one, consider re-fitting specifying the control parameter `parscale`.

## References

## Examples

```
## avoid spurious accuracy
op <- options(digits = 3)
set.seed(123)
x <- rgamma(100, shape = 5, rate = 0.1)
fitdistr(x, "gamma")
## now do this directly with more control.
fitdistr(x, dgamma, list(shape = 1, rate = 0.1), lower = 0.001)

set.seed(123)
x2 <- rt(250, df = 9)
fitdistr(x2, "t", df = 9)
## allow df to vary: not a very good idea!
fitdistr(x2, "t")
## now do fixed-df fit directly with more control.
mydt <- function(x, m, s, df) dt((x-m)/s, df)/s
fitdistr(x2, mydt, list(m = 0, s = 1), df = 9, lower = c(-Inf, 0))

set.seed(123)
x3 <- rweibull(100, shape = 4, scale = 100)
fitdistr(x3, "weibull")

set.seed(123)
x4 <- rnegbin(500, mu = 5, theta = 4)
fitdistr(x4, "Negative Binomial")
options(op)
```

S. Weisberg (1980) *Applied Linear Regression*. Wiley.

fractions

*Rational Approximation***Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

```
fractions(x, cycles = 10, max.denominator = 2000, ...)
```

**Arguments**

<code>x</code>	Any object of mode numeric. Missing values are now allowed.
<code>cycles</code>	The maximum number of steps to be used in the continued fraction approximation process.
<code>max.denominator</code>	An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point.
<code>...</code>	arguments passed to or from other methods.

**Details**

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1/(p_1 + 1/(p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

**Value**

An object of class "fractions". A structure with `.Data` component the same as the input numeric `x`, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth Edition. Springer.

**See Also**

[rational](#)

**Examples**

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
fractions(solve(X, X/5))
fractions(solve(X, X/5)) + 1
```

GAGurine

*Level of GAG in Urine of Children***Description**

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child's GAG concentration is 'normal'.

**Usage**

```
GAGurine
```

**Format**

This data frame contains the following columns:

Age age of child in years.

GAG concentration of GAG (the units have been lost).

**Source**

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

galaxies

*Velocities for 82 Galaxies***Description**

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

**Usage**

```
galaxies
```

**Note**

There is an 83rd measurement of 5607 km/sec in the Postman *et al.* paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

**Source**

Roeder, K. (1990) Density estimation with confidence sets exemplified by superclusters and voids in galaxies. *Journal of the American Statistical Association* **85**, 617–624.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
gal <- galaxies/1000
c(width.SJ(gal, method = "dpi"), width.SJ(gal))
plot(x = c(0, 40), y = c(0, 0.3), type = "n", bty = "l",
      xlab = "velocity of galaxy (1000km/s)", ylab = "density")
rug(gal)
lines(density(gal, width = 3.25, n = 200), lty = 1)
lines(density(gal, width = 2.56, n = 200), lty = 3)
```

---

gamma.dispersion	<i>Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit</i>
------------------	---

---

**Description**

A front end to `gamma.shape` for convenience. Finds the reciprocal of the estimate of the shape parameter only.

**Usage**

```
gamma.dispersion(object, ...)
```

**Arguments**

<code>object</code>	Fitted model object giving the gamma fit.
<code>...</code>	Additional arguments passed on to <code>gamma.shape</code> .

**Value**

The MLE of the dispersion parameter of the gamma distribution.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

[gamma.shape.glm](#), including the example on its help page.

---

gamma.shape	<i>Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit</i>
-------------	--

---

**Description**

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

**Usage**

```
## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
            eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

**Arguments**

object	Fitted model object from a Gamma family or quasi family with variance = "mu^2".
it.lim	Upper limit on the number of iterations.
eps.max	Maximum discrepancy between approximations for the iteration process to continue.
verbose	If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance.
...	further arguments passed to or from other methods.

**Details**

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

**Value**

List of two components

alpha	the maximum likelihood estimate
SE	the approximate standard error, the square-root of the reciprocal of the observed information.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

gehan

*Remission Times of Leukaemia Patients*

---

## Description

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug *6-mercaptopurine* and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

## Usage

gehan

## Format

This data frame contains the following columns:

`pair` label for pair.

`time` remission time in weeks.

`cens` censoring, 0/1.

`treat` treatment, control or 6-MP.

## Source

Cox, D. R. and Oakes, D. (1984) *Analysis of Survival Data*. Chapman & Hall, p. 7. Taken from

Gehan, E.A. (1965) A generalized Wilcoxon test for comparing arbitrarily single-censored samples. *Biometrika* **52**, 203–233.

## References

summary(gehan.cox)
```

---

genotype

*Rat Genotype Data*

---

## Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

## Usage

```
genotype
```

## Format

The data frame has the following components:

`Litter` genotype of the litter.

`Mother` genotype of the foster mother.

`Wt` Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

---

 geyser

*Old Faithful Geyser Data*

---

### Description

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

### Usage

geyser

### Format

A data frame with 299 observations on 2 variables.

duration	numeric	Eruption time in mins
waiting	numeric	Waiting time for this eruption

### Note

The `waiting` time was incorrectly described as the time to the next eruption in the original files, and corrected for **MASS** version 7.3-30.

### References

---

 gilgais

*Line Transect of Soil in Gilgai Territory*

---

### Description

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

**Usage**

```
gilgais
```

**Format**

This data frame contains the following columns:

pH00 pH at depth 0–10 cm.  
 pH30 pH at depth 30–40 cm.  
 pH80 pH at depth 80–90 cm.  
 e00 electrical conductivity in mS/cm (0–10 cm).  
 e30 electrical conductivity in mS/cm (30–40 cm).  
 e80 electrical conductivity in mS/cm (80–90 cm).  
 c00 chloride content in ppm (0–10 cm).  
 c30 chloride content in ppm (30–40 cm).  
 c80 chloride content in ppm (80–90 cm).

 ginv

*Generalized Inverse of a Matrix*

---

**Description**

Calculates the Moore-Penrose generalized inverse of a matrix X.

**Usage**

```
ginv(X, tol = sqrt(.Machine$double.eps))
```

**Arguments**

X                      Matrix for which the Moore-Penrose inverse is required.  
 tol                    A relative tolerance to detect zero singular values.

**Value**

A MP generalized inverse matrix for X.

## References

Venables, W. N. and Ripley, B. D. (1999) *Modern Applied Statistics with S-PLUS*. Third Edition. Springer. p.100.

## See Also

```

---

glm.convert

*Change a Negative Binomial fit to a GLM fit*

---

## Description

This function modifies an output object from `glm.nb()` to one that looks like the output from `glm()` with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

## Usage

```
glm.convert(object)
```

## Arguments

`object`                      An object of class "negbin", typically the output from `glm.nb()`.

## Details

Convenience function needed to effect some low level changes to the structure of the fitted model object.

## Value

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

**See Also**

[glm.nb](#), [negative.binomial](#), [glm](#)

**Examples**

```
quine.nbl <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nbl)
quine.nbB <- update(quine.nbl, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

glm.nb

*Fit a Negative Binomial Generalized Linear Model***Description**

A modification of the system function [glm\(\)](#) to include estimation of the additional parameter, `theta`, for a Negative Binomial generalized linear model.

**Usage**

```
glm.nb(formula, data, weights, subset, na.action,
       start = NULL, etastart, mustart,
       control = glm.control(...), method = "glm.fit",
       model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...,
       init.theta, link = log)
```

**Arguments**

`formula`, `data`, `weights`, `subset`, `na.action`, `start`, `etastart`, `mustart`, `control`, `method`, `model`, `x`, `y`, `contrasts`, `...`  
arguments for the [glm\(\)](#) function. Note that these exclude family and offset (but [offset\(\)](#) can be used).

`init.theta` Optional initial value for the `theta` parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.

`link` The link function. Currently must be one of `log`, `sqrt` or `identity`.

**Details**

An alternating iteration process is used. For given `theta` the GLM is fitted using the same process as used by [glm\(\)](#). For fixed means the `theta` parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating `theta` are controlled by the `maxit` parameter of [glm.control\(\)](#).)

Setting `trace > 0` traces the alternating iteration process. Setting `trace > 1` traces the [glm](#) fit, and setting `trace > 2` traces the estimation of `theta`.

**Value**

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of [glm](#) but contains three additional components, namely `theta` for the ML estimate of `theta`, `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

---

glmmPQL

---

*Fit Generalized Linear Mixed Models via PQL*

---

## Description

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

## Usage

```
glmmPQL(fixed, random, family, data, correlation, weights,
        control, niter = 10, verbose = TRUE, ...)
```

## Arguments

<code>fixed</code>	a two-sided linear formula giving fixed-effects part of the model.
<code>random</code>	a formula or list of formulae describing the random effects.
<code>family</code>	a GLM family.
<code>data</code>	an optional data frame used as the first place to find variables in the formulae, weights and if present in <code>...</code> , subset.
<code>correlation</code>	an optional correlation structure.
<code>weights</code>	optional case weights as in <code>glm</code> .
<code>control</code>	an optional argument to be passed to <code>lme</code> .
<code>niter</code>	maximum number of iterations.
<code>verbose</code>	logical: print out record of iterations?
<code>...</code>	Further arguments for <code>lme</code> .

## Details

glmmPQL works by repeated calls to [lme](#), so package `nlme` will be loaded at first use if necessary.

## Value

A object of class `"lme"`: see [lmeObject](#).

huber

*Huber M-estimator of Location with MAD Scale*

---

## Description

Finds the Huber M-estimator of location with MAD scale.

## Usage

```
huber(y, k = 1.5, tol = 1e-06)
```

## Arguments

y	vector of data values
k	Winsorizes at k standard deviations
tol	convergence tolerance

## Value

list of location and scale parameters

mu	location estimate
s	MAD scale estimate

**References**

hubers	<i>Huber Proposal 2 Robust Estimator of Location and/or Scale</i>
--------	---

---

**Description**

Finds the Huber M-estimator for location with scale specified, scale with location specified, or both if neither is specified.

**Usage**

```
hubers(y, k = 1.5, mu, s, initmu = median(y), tol = 1e-06)
```

**Arguments**

y	vector y of data values
k	Winsorizes at k standard deviations
mu	specified location
s	specified scale
initmu	initial value of mu
tol	convergence tolerance

**Value**

list of location and scale estimates	
mu	location estimate
s	scale estimate

immer

*Yields from a Barley Field Trial*

---

## Description

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

## Usage

```
immer
```

## Format

This data frame contains the following columns:

`Loc` The location.

`Var` The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").

`Y1` Yield in 1931.

`Y2` Yield in 1932.

## Source

Immer, F.R., Hayes, H.D. and LeRoy Powers (1934) Statistical determination of barley varietal adaptation. *Journal of the American Society for Agronomy* **26**, 403–419.

Fisher, R.A. (1947) *The Design of Experiments*. 4th edition. Edinburgh: Oliver and Boyd.

## References

## Examples

```
immer.aov <- aov(cbind(Y1,Y2) ~ Loc + Var, data = immer)
summary(immer.aov)

immer.aov <- aov((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
```

---

Insurance

*Numbers of Car Insurance claims*

---

### Description

The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

### Usage

`Insurance`

### Format

This data frame contains the following columns:

`District` factor: district of residence of policyholder (1 to 4): 4 is major cities.

`Group` an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.

`Age` an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.

`Holders` numbers of policyholders.

`Claims` numbers of claims

### Source

L. A. Baxter, S. M. Coutts and G. A. F. Ross (1980) Applications of linear models in motor insurance. *Proceedings of the 21st International Congress of Actuaries, Zurich* pp. 11–29.

### Examples

```
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
     data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```

isoMDS

*Kruskal's Non-metric Multidimensional Scaling***Description**

One form of non-metric multidimensional scaling

**Usage**

```
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
       tol = 1e-3, p = 2)
```

```
Shepard(d, x, p = 2)
```

**Arguments**

d	distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed.
y	An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution, unless there are missing or infinite dissimilarities.
k	The desired dimension for the solution, passed to <code>cmdscale</code> .
maxit	The maximum number of iterations.
trace	Logical for tracing optimization. Default <code>TRUE</code> .
tol	convergence tolerance.
p	Power for Minkowski distance in the configuration space.
x	A final configuration.

**Details**

This chooses a  $k$ -dimensional (default  $k = 2$ ) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since for the default  $p = 2$  the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

**Value**

Two components:

points	A $k$ -column vector of the fitted configuration.
stress	The final stress achieved (in percent).

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

---

kde2d

---

*Two-Dimensional Kernel Density Estimation*

---

## Description

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

## Usage

```
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

## Arguments

<code>x</code>	x coordinate of data
<code>y</code>	y coordinate of data
<code>h</code>	vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see <a href="#">bandwidth.nrd</a> ). A scalar value will be taken to apply to both directions.
<code>n</code>	Number of grid points in each direction. Can be scalar or a length-2 integer vector.
<code>lims</code>	The limits of the rectangle covered by the grid as <code>c(xl, xu, yl, yu)</code> .

## Value

A list of three components.

<code>x</code> , <code>y</code>	The x and y coordinates of the grid points, vectors of length <code>n</code> .
<code>z</code>	An <code>n[1]</code> by <code>n[2]</code> matrix of the estimated density: rows correspond to the value of <code>x</code> , columns to the value of <code>y</code> .

 lda

*Linear Discriminant Analysis*

---

## Description

Linear discriminant analysis.

## Usage

```
lda(x, ...)
```

## S3 method for class 'formula'

```
lda(formula, data, ..., subset, na.action)
```

## Default S3 method:

```
lda(x, grouping, prior = proportions, tol = 1.0e-4,
    method, CV = FALSE, nu, ...)
```

## S3 method for class 'data.frame'

```
lda(x, ...)
```

## S3 method for class 'matrix'

```
lda(x, grouping, ..., subset, na.action)
```

## Arguments

<code>formula</code>	A formula of the form <code>groups ~ x1 + x2 + ...</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
<code>data</code>	Data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>x</code>	(required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
<code>grouping</code>	(required if no formula principal argument is given.) a factor specifying the class for each observation.
<code>prior</code>	the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.
<code>tol</code>	A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than <code>tol^2</code> .
<code>subset</code>	An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
<code>method</code>	"moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a <i>t</i> distribution.
<code>CV</code>	If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
<code>nu</code>	degrees of freedom for <code>method = "t"</code> .
<code>...</code>	arguments passed to or from other methods.

## Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the `prior` will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

## Value

If `CV = TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

`prior`                    the prior probabilities used.

means	the group means.
scaling	a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.
svd	the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.
N	The number of observations used.
call	The (matched) function call.

**Note**

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but `subset=` and `na.action=`, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using `update()` in the usual way.

---

ldahist	<i>Histograms or Density Plots of Multiple Groups</i>
---------	---

---

**Description**

Plot histograms or density plots of data on a single Fisher linear discriminant.

**Usage**

```
ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,
        xlim = range(breaks), ymax = 0, width,
        type = c("histogram", "density", "both"),
        sep = (type != "density"),
        col = 5, xlab = deparse(substitute(data)), bty = "n", ...)
```

**Arguments**

<code>data</code>	vector of data. Missing values (NAs) are allowed and omitted.
<code>g</code>	factor or vector giving groups, of the same length as <code>data</code> .
<code>nbins</code>	Suggested number of bins to cover the whole range of the data.
<code>h</code>	The bin width (takes precedence over <code>nbins</code> ).
<code>x0</code>	Shift for the bins - the breaks are at $x0 + h * (... , -1, 0, 1, ...)$
<code>breaks</code>	The set of breakpoints to be used. (Usually omitted, takes precedence over <code>h</code> and <code>nbins</code> ).
<code>xlim</code>	The limits for the x-axis.
<code>ymax</code>	The upper limit for the y-axis.
<code>width</code>	Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately.
<code>type</code>	Type of plot.
<code>sep</code>	Whether there is a separate plot for each group, or one combined plot.
<code>col</code>	The colour number for the bar fill.
<code>xlab</code>	label for the plot x-axis. By default, this will be the name of <code>data</code> .
<code>bty</code>	The box type for the plot - defaults to none.
<code>...</code>	additional arguments to <code>polygon</code> .

**Side Effects**

Histogram and/or density plots are plotted on the current device.

leuk

---

*Survival Times and White Blood Counts for Leukaemia Patients*

---

**Description**

A data frame of data from 33 leukaemia patients.

**Usage**

leuk

**Format**

A data frame with columns:

wbc white blood count.

ag a test result, "present" or "absent".

time survival time in weeks.

**Details**

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient's white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

**Examples**

```
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```

---

lm.gls*Fit Linear Models by Generalized Least Squares*

---

## Description

Fit linear models by Generalized Least Squares

## Usage

```
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
        method = "qr", model = FALSE, x = FALSE, y = FALSE,
        contrasts = NULL, ...)
```

## Arguments

formula	a formula expression as for regression models, of the form response ~ predictors. See the documentation of formula for other details.
data	an optional data frame in which to interpret the variables occurring in formula.
W	a weight matrix.
subset	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
na.action	a function to filter missing data.
inverse	logical: if true W specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
method	method to be used by <code>lm.fit</code> .
model	should the model frame be returned?
x	should the design matrix be returned?
y	should the response be returned?
contrasts	a list of contrasts to be used for some or all of
...	additional arguments to <code>lm.fit</code> .

## Details

The problem is transformed to uncorrelated form and passed to `lm.fit`.

## Value

An object of class "lm.gls", which is similar to an "lm" object. There is no "weights" component, and only a few "lm" methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

## See Also

---

lm.ridge	<i>Ridge Regression</i>
----------	-------------------------

---

**Description**

Fit a linear model by ridge regression.

**Usage**

```
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
         x = FALSE, y = FALSE, contrasts = NULL, ...)
```

**Arguments**

formula	a formula expression as for regression models, of the form response ~ predictors. See the documentation of formula for other details. <a href="#">offset</a> terms are allowed.
data	an optional data frame in which to interpret the variables occurring in formula.
subset	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
na.action	a function to filter missing data.
lambda	A scalar or vector of ridge constants.
model	should the model frame be returned? Not implemented.
x	should the design matrix be returned? Not implemented.
y	should the response be returned? Not implemented.
contrasts	a list of contrasts to be used for some or all of factor terms in the formula. See the contrasts.arg of <a href="#">model.matrix.default</a> .
...	additional arguments to <a href="#">lm.fit</a> .

**Details**

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

**Value**

A list with components

coef	matrix of coefficients, one row for each value of lambda. Note that these are not on the original scale and are for use by the <a href="#">coef</a> method.
scales	scalings used on the X matrix.
Inter	was intercept included?
lambda	vector of lambda values
ym	mean of y
xm	column means of x matrix
GCV	vector of GCV values
kHKB	HKB estimate of the ridge constant.
kLW	L-W estimate of the ridge constant.

```

---

loglm

---

*Fit Log-Linear Models by Iterative Proportional Scaling*

---

## Description

This function provides a front-end to the standard function, `loglin`, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as `glm`.

## Usage

```
loglm(formula, data, subset, na.action, ...)
```

## Arguments

formula	<p>A linear model formula specifying the log-linear model.</p> <p>If the left-hand side is empty, the <code>data</code> argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the <code>dimnames</code> attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the <code>data</code> argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a <code>.</code> to stand for ‘all other variables in the data frame’ is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.</p>
data	<p>Numeric array or data frame. In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way.</p> <p>This argument may be the result of a call to <a href="#">xtabs</a>.</p>
subset	<p>Specifies a subset of the rows in the data frame to be used. The default is to take all rows.</p>
na.action	<p>Specifies a method for handling missing observations. The default is to fail if missing values are present.</p>
...	<p>May supply other arguments to the function <a href="#">loglm1</a>.</p>

## Details

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

## Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

## Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

logtrans

*Estimate log Transformation Parameter***Description**

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form  $\log(y + \alpha) \sim x_1 + x_2 + \dots$ .

**Usage**

```

logtrans(object, ...)

## Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
         plotit = TRUE, interp =, xlab = "alpha",
         ylab = "log Likelihood")

## S3 method for class 'formula'
logtrans(object, data, ...)

## S3 method for class 'lm'
logtrans(object, ...)

```

**Arguments**

**object** Fitted linear model object, or formula defining the untransformed model that is  $y \sim x_1 + x_2 + \dots$ . The function is generic.

...	If object is a formula, this argument may specify a data frame as for <code>lm</code> .
alpha	Set of values for the transformation parameter, <code>alpha</code> .
plotit	Should plotting be done?
interp	Should the marginal log-likelihood be interpolated with a spline approximation? (Default is <code>TRUE</code> if plotting is to be done and the number of real points is less than 100.)
xlab	as for <code>plot</code> .
ylab	as for <code>plot</code> .
data	optional data argument for <code>lm</code> fit.

Value

List with components `x` (for `alpha`) and `y` (for the marginal log-likelihood values).

Side Effects

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

```

---

lqs	<i>Resistant Regression</i>
-----	-----------------------------

---

Description

Fit a regression to the *good* points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.

Usage

```
lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ...,
    method = c("lts", "lqs", "lms", "S", "model.frame"),
    subset, na.action, model = TRUE,
    x.ret = FALSE, y.ret = FALSE, contrasts = NULL)
```

```
## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
    quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)
```

## Arguments

<code>formula</code>	a formula of the form $y \sim x_1 + x_2 + \dots$
<code>data</code>	data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>subset</code>	an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)
<code>na.action</code>	function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include <code>na.omit</code> and <code>na.exclude</code> , which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.)
<code>model, x.ret, y.ret</code>	logical. If TRUE the model frame, the model matrix and the response are returned, respectively.
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>x</code>	a matrix or data frame containing the explanatory variables.
<code>y</code>	the response: a vector of length the number of rows of <code>x</code> .
<code>intercept</code>	should the model include an intercept?
<code>method</code>	the method to be used. <code>model.frame</code> returns the model frame: for the others see the Details section. Using <code>lmsreg</code> or <code>ltsreg</code> forces "lms" and "lts" respectively.
<code>quantile</code>	the quantile to be used: see Details. This is over-ridden if <code>method = "lms"</code> .
<code>control</code>	additional control items: see Details.
<code>k0</code>	the cutoff / tuning constant used for $\chi()$ and $\psi()$ functions when <code>method = "S"</code> , currently corresponding to Tukey's 'biweight'.
<code>seed</code>	the seed to be used for random sampling: see <code>.Random.seed</code> . The current value of <code>.Random.seed</code> will be preserved if it is set..
<code>...</code>	arguments to be passed to <code>lqs.default</code> or <code>lqs.control</code> , see <code>control</code> above and Details.

## Details

Suppose there are  $n$  data points and  $p$  regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for `quantile`, which are `floor((n+p+1)/2)` and `floor((n+1)/2)` respectively. For "lts" the default is `floor(n/2) + floor((p+1)/2)`.

The "S" estimation method solves for the scale  $s$  such that the average of a function  $\chi$  of the residuals divided by  $s$  is equal to a given constant.

The `control` argument is a list with components

`psamp`: the size of each sample. Defaults to `p`.  
`nsamp`: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is  $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.  
`adjust`: should the intercept be optimized for each sample? Defaults to `TRUE`.

### Value

An object of class "lqs". This is a list with components

<code>crit</code>	the value of the criterion for the best solution found, in the case of <code>method == "S"</code> before IWLS refinement.
<code>sing</code>	character. A message about the number of samples which resulted in singular fits.
<code>coefficients</code>	of the fitted linear model
<code>bestone</code>	the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
<code>fitted.values</code>	the fitted values.
<code>residuals</code>	the residuals.
<code>scale</code>	estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for <code>method == "S"</code> ) is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

### Note

There seems no reason other than historical to use the `lms` and `lqs` options. LMS estimation is of low efficiency (converging at rate  $n^{-1/3}$ ) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of  $(\text{floor}((n-p)/2) + 1)/n$  attained if  $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$ . The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if `n` is large and `p` small.

Opinions differ over the choice of `psamp`. Rousseeuw and Hubert (1997) only consider `p`; Marazzi (1993) recommends `p+1` and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

`mca`

---

*Multiple Correspondence Analysis*

---

**Description**

Computes a multiple correspondence analysis of a set of factors.

**Usage**

```
mca(df, nf = 2, abbrev = FALSE)
```

**Arguments**

<code>df</code>	A data frame containing only factors
<code>nf</code>	The number of dimensions for the MCA. Rarely 3 might be useful.
<code>abbrev</code>	Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if <code>abbrev = TRUE</code> they are just ‘level’ which will suffice if the factors have distinct levels.

**Value**

An object of class "mca", with components

<code>rs</code>	The coordinates of the rows, in <code>nf</code> dimensions.
<code>cs</code>	The coordinates of the column vertices, one for each level of each factor.
<code>fs</code>	Weights for each row, used to interpolate additional factors in <code>predict.mca</code> .
<code>p</code>	The number of factors
<code>d</code>	The singular values for the <code>nf</code> dimensions.
<code>call</code>	The matched call.

minn38

*Minnesota High School Graduates of 1938***Description**

The Minnesota high school graduates of 1938 were classified according to four factors, described below. The `minn38` data frame has 168 rows and 5 columns.

**Usage**

minn38

**Format**

This data frame contains the following columns:

`hs` high school rank: "L", "M" and "U" for lower, middle and upper third.

`phs` post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").

`fol` father's occupational level, (seven levels, "F1", "F2", ..., "F7").

`sex` sex: factor with levels "F" or "M".

`f` frequency.

```

muscle

*Effect of Calcium Chloride on Muscle Contraction in Rat Hearts*

## Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

## Usage

```
muscle
```

## Format

This data frame contains the following columns:

Strip which heart muscle strip was used?

Conc concentration of calcium chloride solution, in multiples of 2.2 mM.

Length the change in length (shortening) of the strip, (allegedly) in mm.

## Source

## Examples

```
A <- model.matrix(~ Strip - 1, data=muscle)
rats.nls1 <- nls(log(Length) ~ cbind(A, rho^Conc),
  data = muscle, start = c(rho=0.1), algorithm="plinear")
(B <- coef(rats.nls1))

st <- list(alpha = B[2:22], beta = B[23], rho = B[1])
(rats.nls2 <- nls(log(Length) ~ alpha[Strip] + beta*rho^Conc,
  data = muscle, start = st))

Muscle <- with(muscle, {
  Muscle <- expand.grid(Conc = sort(unique(Conc)), Strip = levels(Strip))
  Muscle$Yhat <- predict(rats.nls2, Muscle)
  Muscle <- cbind(Muscle, logLength = rep(as.numeric(NA), 126))
```

```

ind <- match(paste(Strip, Conc),
             paste(Muscle$Strip, Muscle$Conc))
Muscle$logLength[ind] <- log(Length)
Muscle})

lattice::xyplot(Yhat ~ Conc | Strip, Muscle, as.table = TRUE,
  ylim = range(c(Muscle$Yhat, Muscle$logLength), na.rm = TRUE),
  subscripts = TRUE, xlab = "Calcium Chloride concentration (mM)",
  ylab = "log(Length in mm)", panel =
  function(x, y, subscripts, ...) {
    panel.xyplot(x, Muscle$logLength[subscripts], ...)
    llines(spline(x, y))
  })

```

mvnorm

*Simulate from a Multivariate Normal Distribution***Description**

Produces one or more samples from the specified multivariate normal distribution.

**Usage**

```
mvnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)
```

**Arguments**

<code>n</code>	the number of samples required.
<code>mu</code>	a vector giving the means of the variables.
<code>Sigma</code>	a positive-definite symmetric matrix specifying the covariance matrix of the variables.
<code>tol</code>	tolerance (relative to largest variance) for numerical lack of positive-definiteness in <code>Sigma</code> .
<code>empirical</code>	logical. If true, <code>mu</code> and <code>Sigma</code> specify the empirical not population mean and covariance matrix.
<code>EISPACK</code>	logical: values other than <code>FALSE</code> are an error.

**Details**

The matrix decomposition is done via `eigen`; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

**Value**

If `n = 1` a vector of the same length as `mu`, otherwise an `n` by `length(mu)` matrix with one sample in each row.

**Side Effects**

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.

negative.binomial    *Family function for Negative Binomial GLMs*

---

## Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known `theta` parameter, using `glm()`.

## Usage

```
negative.binomial(theta = stop("'theta' must be specified"), link = "log")
```

## Arguments

<code>theta</code>	The known value of the additional parameter, <code>theta</code> .
<code>link</code>	The link function, as a character string, name or one-element character vector specifying one of <code>log</code> , <code>sqrt</code> or <code>identity</code> , or an object of class <code>"link-glm"</code> .

## Value

An object of class `"family"`, a list of functions and expressions needed by `glm()` to fit a Negative Binomial generalized linear model.

## References

nlschools

*Eighth-Grade Pupils in the Netherlands***Description**

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

**Usage**

nlschools

**Format**

This data frame contains 2287 rows and the following columns:

lang language test score.

IQ verbal IQ.

class class ID.

GS class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).

SES social-economic status of pupil's family.

COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

```

---

npk

---

*Classical N, P, K Factorial Experiment*

---

## Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

## Usage

```
npk
```

## Format

The npk data frame has 24 rows and 5 columns:

`block` which block (label 1 to 6).

`N` indicator (0/1) for the application of nitrogen.

`P` indicator (0/1) for the application of phosphate.

`K` indicator (0/1) for the application of potassium.

`yield` Yield of peas, in pounds/plot (the plots were (1/70) acre).

## Note

This dataset is also contained in R 3.0.2 and later.

npr1

*US Naval Petroleum Reserve No. 1 data***Description**

Data on the locations, porosity and permeability (a measure of oil flow) on 104 oil wells in the US Naval Petroleum Reserve No. 1 in California.

**Usage**

npr1

**Format**

This data frame contains the following columns:

`x` x coordinates, in miles (origin unspecified)..

`y` y coordinates, in miles.

`perm` permeability in milli-Darcies.

`por` porosity (%).

**Source**

Null

*Null Spaces of Matrices***Description**

Given a matrix,  $M$ , find a matrix  $N$  giving a basis for the (left) null space. That is  $\text{crossprod}(N, M) = \mathbf{t}(N) \%*\% M$  is an all-zero matrix and  $N$  has the maximum number of linearly independent columns.

**Usage**

```
Null(M)
```

**Arguments**

$M$                       Input matrix. A vector is coerced to a 1-column matrix.

**Details**

For a basis for the (right) null space  $\{x : Mx = 0\}$ , use `Null(t(M))`.

**Value**

The matrix  $N$  with the basis for the (left) null space, or a matrix with zero columns if the matrix  $M$  is square and of maximal rank.

# The function is currently defined as
function(M)
{
  tmp <- qr(M)
  set <- if(tmp$rank == 0L) seq_len(ncol(M)) else -seq_len(tmp$rank)
  qr.Q(tmp, complete = TRUE)[, set, drop = FALSE]
}
```

oats

*Data from an Oats Field Trial***Description**

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

**Usage**

oats

**Format**

This data frame contains the following columns:

B Blocks, levels I, II, III, IV, V and VI.

V Varieties, 3 levels.

N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.

Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

```

---

OME	<i>Tests of Auditory Perception in Children with OME</i>
-----	--

---

**Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

**Usage**

OME

**Format**

The OME data frame has 1129 rows and 7 columns:

ID Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.

OME "low" or "high" or "N/A" (at ages other than 30 and 60 months).

Age Age of the subject (months).

Loud Loudness of stimulus, in decibels.

Noise Whether the signal in the stimulus was "coherent" or "incoherent".

Correct Number of correct responses from Trials trials.

Trials Number of trials performed.

**Background**

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term ‘binaural hearing’ is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

painters

*The Painter's Data of de Piles*

---

## Description

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

## Usage

painters

## Format

The row names of the data frame are the painters. The components are:

Composition Composition score.

Drawing Drawing score.

Colour Colour score.

Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows:

"A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F": Sixteenth Century; "G": Seventeenth Century; "H": French.

pairs.lda

*Produce Pairwise Scatterplots from an 'lda' Fit*

---

## Description

Pairwise scatterplot of the data on the linear discriminants.

## Usage

```
## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.lda,
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

## Arguments

x	Object of class "lda".
labels	vector of character strings for labelling the variables.
panel	panel function to plot the data in each panel.
dimen	The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.
abbrev	whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
...	additional arguments for pairs.default.
cex	graphics parameter cex for labels on plots.
type	type of plot. The default is in the style of pairs.default; the style "trellis" uses the Trellis function splom.

## Details

This function is a method for the generic function `pairs()` for class `"lda"`. It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

parcoord	<i>Parallel Coordinates Plot</i>
----------	----------------------------------

---

## Description

Parallel coordinates plot

## Usage

```
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

## Arguments

<code>x</code>	a matrix or data frame who columns represent variables. Missing values are allowed.
<code>col</code>	A vector of colours, recycled as necessary for each observation.
<code>lty</code>	A vector of line types, recycled as necessary for each observation.
<code>var.label</code>	If TRUE, each variable's axis is labelled with maximum and minimum values.
<code>...</code>	Further graphics parameters which are passed to <code>matplot</code> .

## Side Effects

a parallel coordinates plots is drawn.

`petrol`*N. L. Prater's Petrol Refinery Data*

---

### Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

### Usage

```
petrol
```

### Format

The variables are as follows

No crude oil sample identification label. (Factor.)

SG specific gravity, degrees API. (Constant within sample.)

VP vapour pressure in pounds per square inch. (Constant within sample.)

V10 volatility of crude; ASTM 10% point. (Constant within sample.)

EP desired volatility of gasoline. (The end point. Varies within sample.)

Y yield as a percentage of crude.

### Source

N. H. Prater (1956) Estimate gasoline yields from crudes. *Petroleum Refiner* **35**, 236–238.

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.

### References

Pima.tr*Diabetes in Pima Indian Women*

---

## Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

## Usage

Pima.tr  
Pima.tr2  
Pima.te

## Format

These data frames contains the following columns:

npreg number of pregnancies.  
glu plasma glucose concentration in an oral glucose tolerance test.  
bp diastolic blood pressure (mm Hg).  
skin triceps skin fold thickness (mm).  
bmi body mass index (weight in kg/(height in m)<sup>2</sup>).  
ped diabetes pedigree function.  
age age in years.  
type Yes or No, for diabetic according to WHO criteria.

## Details

The training set Pima.tr contains a randomly selected set of 200 subjects, and Pima.te contains the remaining 332 subjects. Pima.tr2 contains Pima.tr plus 100 subjects with missing values in the explanatory variables.

plot.lda

*Plot Method for Class 'lda'***Description**

Plots a set of data on one, two or more linear discriminants.

**Usage**

```
## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
      abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

**Arguments**

x	An object of class "lda".
panel	the panel function used to plot the data.
...	additional arguments to pairs, ldahist or eqscplot.
cex	graphics parameter cex for labels on plots.
dimen	The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.
abbrev	whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
xlab	label for the x axis
ylab	label for the y axis

**Details**

This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object x of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a pairs plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

plot.mca

*Plot Method for Objects of Class 'mca'***Description**

Plot a multiple correspondence analysis.

**Usage**

```
## S3 method for class 'mca'
plot(x, rows = TRUE, col, cex = par("cex"), ...)
```

**Arguments**

x	An object of class "mca".
rows	Should the coordinates for the rows be plotted, or just the vertices for the levels?
col, cex	The colours and cex to be used for the row points and level vertices respectively.
...	Additional parameters to plot.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

[mca](#), [predict.mca](#)

**Examples**

```
plot(mca(farms, abbrev = TRUE))
```

plot.profile

*Plotting Functions for 'profile' Objects***Description**

[plot](#) and [pairs](#) methods for objects of class "profile".

**Usage**

```
## S3 method for class 'profile'
plot(x, ...)
## S3 method for class 'profile'
pairs(x, colours = 2:3, ...)
```

**Arguments**

x	an object inheriting from class "profile".
colours	Colours to be used for the mean curves conditional on x and y respectively.
...	arguments passed to or from other methods.

## Details

This is the main `plot` method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters  $x$  and  $y$ , two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of  $y|x$  and  $x|y$ , and the contours would be exactly elliptical.

## Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

## See Also

`profile.glm`, `profile.nls`.

## Examples

```
## see ?profile.glm for an example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fml <- nls(demand ~ SSasymptOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fml, alpha = 0.1)
MASS:::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

---

polr

*Ordered Logistic or Probit Regression*

---

## Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

## Usage

```
polr(formula, data, weights, start, ..., subset, na.action,
      contrasts = NULL, Hess = FALSE, model = TRUE,
      method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```

## Arguments

<code>formula</code>	a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of <code>formula</code> for other details.
<code>data</code>	an optional data frame in which to interpret the variables occurring in <code>formula</code> .
<code>weights</code>	optional case weights in fitting. Default to 1.
<code>start</code>	initial values for the parameters. This is in the format <code>c(coefficients, zeta)</code> : see the Values section.
<code>...</code>	additional arguments to be passed to <code>optim</code> , most often a <code>control</code> argument.
<code>subset</code>	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
<code>na.action</code>	a function to filter missing data.
<code>contrasts</code>	a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
<code>Hess</code>	logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call <code>summary</code> or <code>vcov</code> on the fit.
<code>model</code>	logical for whether the model matrix should be returned.
<code>method</code>	logistic or probit or (complementary) log-log or <code>cauchit</code> (corresponding to a Cauchy latent variable).

## Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable  $Y_i$  which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin  $Y_i$  falls into with breakpoints

$$\zeta_0 = -\infty < \zeta_1 < \dots < \zeta_K = \infty$$

This leads to the model

$$\text{logit}P(Y \leq k|x) = \zeta_k - \eta$$

with *logit* replaced by *probit* for a normal latent variable, and  $\eta$  being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for  $\eta$  (and hence the coefficients `beta`).

In the logistic case, the left-hand side of the last display is the log odds of category  $k$  or less, and since these are log odds which differ only by a constant for different  $k$ , the odds are proportional. Hence the term *proportional odds logistic regression*.

The log-log and complementary log-log links are the increasing functions  $F^{-1}(p) = -\log(-\log(p))$  and  $F^{-1}(p) = \log(-\log(1 - p))$ ; some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A *proportional hazards* model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

`predict`, `summary`, `vcov`, `anova`, `model.frame` and an `extractAIC` method for use with `stepAIC` (and `step`). There are also `profile` and `confint` methods.

**Value**

A object of class "polr". This has components

<code>coefficients</code>	the coefficients of the linear predictor, which has no intercept.
<code>zeta</code>	the intercepts for the class boundaries.
<code>deviance</code>	the residual deviance.
<code>fitted.values</code>	a matrix, with a column for each level of the response.
<code>lev</code>	the names of the response levels.
<code>terms</code>	the <code>terms</code> structure describing the model.
<code>df.residual</code>	the number of residual degrees of freedoms, calculated using the weights.
<code>edf</code>	the (effective) number of degrees of freedom used by the model
<code>n, nobs</code>	the (effective) number of observations, calculated using the weights. ( <code>nobs</code> is for use by <a href="#">stepAIC</a> ).
<code>call</code>	the matched call.
<code>method</code>	the matched method used.
<code>convergence</code>	the convergence code returned by <code>optim</code> .
<code>niter</code>	the number of function and gradient evaluations used by <code>optim</code> .
<code>lp</code>	the linear predictor (including any offset).
<code>Hessian</code>	(if <code>Hess</code> is true). Note that this is a numerical approximation derived from the optimization proces.
<code>model</code>	(if <code>model</code> is true).

**Note**

The [vcov](#) method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, `method = "cloglog"` confusingly gave the log-log link, implicitly assuming the first response level was the ‘best’.

---

predict.glmmPQL	<i>Predict Method for glmmPQL Fits</i>
-----------------	--

---

## Description

Obtains predictions from a fitted generalized linear model with random effects.

## Usage

```
## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
        level, na.action = na.pass, ...)
```

## Arguments

<code>object</code>	a fitted object of class inheriting from "glmmPQL".
<code>newdata</code>	optionally, a data frame in which to look for variables with which to predict.
<code>type</code>	the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and <code>type = "response"</code> gives the predicted probabilities.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
<code>na.action</code>	function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.
<code>...</code>	further arguments passed to or from other methods.

## Value

If `level` is a single integer, a vector otherwise a data frame.

## See Also

[glmmPQL](#), [predict.lme](#).

## Examples

```
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
              family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

---

predict.lda

*Classify Multivariate Observations by Linear Discrimination*

---

## Description

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

## Usage

```
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
        method = c("plug-in", "predictive", "debiased"), ...)
```

## Arguments

<code>object</code>	object of class "lda"
<code>newdata</code>	data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lda</code> object.
<code>prior</code>	The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>lda</code> .
<code>dimen</code>	the dimension of the space to be used. If this is less than <code>min(p, ng-1)</code> , only the first <code>dimen</code> discriminant components are used (except for <code>method="predictive"</code> ), and only those dimensions are returned in <code>x</code> .
<code>method</code>	This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
<code>...</code>	arguments based from or to other methods

## Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.

**Value**

a list with components

class	The MAP classification (a factor)
posterior	posterior probabilities for the classes
x	the scores of test cases on up to <code>dimen</code> discriminant variables

**References**

test <- rbind(iris3[-tr,,1], iris3[-tr,,2], iris3[-tr,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
z <- lda(train, cl)
predict(z, test)$class
```

---

predict.lqs	<i>Predict from an lqs Fit</i>
-------------	--------------------------------

---

**Description**

Predict from an resistant regression fitted by `lqs`.

**Usage**

```
## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

**Arguments**

object	object inheriting from class "lqs"
newdata	matrix or data frame of cases to be predicted or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lqs</code> object.
na.action	function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.
...	arguments to be passed from or to other methods.

**Details**

This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

**Value**

A vector of predictions.

**Author(s)**

B.D. Ripley

**See Also**

[lqs](#)

**Examples**

```
set.seed(123)
fm <- lqs(stack.loss ~ ., data = stackloss, method = "S", nsamp = "exact")
predict(fm, stackloss)
```

---

predict.mca

*Predict Method for Class 'mca'*

---

**Description**

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

**Usage**

```
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

**Arguments**

<code>object</code>	An object of class <code>"mca"</code> , usually the result of a call to <code>mca</code> .
<code>newdata</code>	A data frame containing <i>either</i> additional rows of the factors used to fit <code>object</code> <i>or</i> additional factors for the cases used in the original fit.
<code>type</code>	Are predictions required for further rows or for new factors?
<code>...</code>	Additional arguments from <code>predict</code> : unused.

**Value**

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

predict.qda

*Classify from Quadratic Discriminant Analysis*

---

## Description

Classify multivariate observations in conjunction with `qda`

## Usage

```
## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
        method = c("plug-in", "predictive", "debiased", "looCV"), ...)
```

## Arguments

<code>object</code>	object of class "qda"
<code>newdata</code>	data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>qda</code> object.
<code>prior</code>	The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>qda</code> .
<code>method</code>	This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned.
<code>...</code>	arguments based from or to other methods

## Details

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

**Value**

a list with components

class	The MAP classification (a factor)
posterior	posterior probabilities for the classes

**References**

predict(zq, test)$class
```

---

profile.glm

*Method for Profiling glm Objects*

---

**Description**

Investigates the profile log-likelihood function for a fitted model of class "glm".

**Usage**

```
## S3 method for class 'glm'
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
       del = zmax/5, trace = FALSE, ...)
```

**Arguments**

fitted	the original fitted model object.
which	the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
alpha	highest significance level allowed for the profile t-statistics.
maxsteps	maximum number of points to be used for profiling each parameter.
del	suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
trace	logical: should the progress of profiling be reported?
...	further arguments passed to or from other methods.

**Details**

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

**Value**

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

`par.vals`            a matrix of parameter values for each fitted model.  
`tau`                 the profile t-statistics.

**Author(s)**

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

**Examples**

```
options(contrasts = c("contr.treatment", "contr.poly"))
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

---

qda

---

*Quadratic Discriminant Analysis*

---

**Description**

Quadratic discriminant analysis.

**Usage**

```
qda(x, ...)

## S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
qda(x, ...)
```

```
## S3 method for class 'matrix'
qda(x, grouping, ..., subset, na.action)
```

### Arguments

<code>formula</code>	A formula of the form <code>groups ~ x1 + x2 + ...</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
<code>data</code>	Data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>x</code>	(required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
<code>grouping</code>	(required if no formula principal argument is given.) a factor specifying the class for each observation.
<code>prior</code>	the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.
<code>subset</code>	An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
<code>method</code>	"moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a t distribution.
<code>CV</code>	If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
<code>nu</code>	degrees of freedom for <code>method = "t"</code> .
<code>...</code>	arguments passed to or from other methods.

### Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

### Value

an object of class "qda" containing the following components:

<code>prior</code>	the prior probabilities used.
<code>means</code>	the group means.
<code>scaling</code>	for each group <code>i</code> , <code>scaling[, , i]</code> is an array which transforms observations so that within-groups covariance matrix is spherical.
<code>ldet</code>	a vector of half log determinants of the dispersion matrix.
<code>lev</code>	the levels of the grouping factor.
<code>terms</code>	(if formula is a formula) an object of mode expression and class term summarizing the formula.

call the (matched) function call.

unless CV=TRUE, when the return value is a list with components:

class The MAP classification (a factor)  
posterior posterior probabilities for the classes

---

quine

*Absenteeism from School in Rural New South Wales*

---

## Description

The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

## Usage

quine

## Format

This data frame contains the following columns:

Eth ethnic background: Aboriginal or Not, ("A" or "N").  
Sex sex: factor with levels ("F" or "M").  
Age age group: Primary ("F0"), or forms "F1", "F2" or "F3".  
Lrn learner status: factor with levels Average or Slow learner, ("AL" or "SL").  
Days days absent from school in the year.

Rabbit

---

*Blood Pressure in Rabbits*

---

## Description

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the  $5-HT_3$  antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of  $5-HT_3$  receptors.

## Usage

Rabbit

## Format

This data frame contains 60 rows and the following variables:

`BPchange` change in blood pressure relative to the start of the experiment.

`Dose` dose of Phenylbiguanide in micrograms.

`Run` label of run ("C1" to "C5", then "M1" to "M5").

`Treatment` placebo or the  $5-HT_3$  antagonist MDL 72222.

`Animal` label of animal used ("R1" to "R5").

`rational`*Rational Approximation*

---

### Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

### Usage

```
rational(x, cycles = 10, max.denominator = 2000, ...)
```

### Arguments

<code>x</code>	Any object of mode numeric. Missing values are now allowed.
<code>cycles</code>	The maximum number of steps to be used in the continued fraction approximation process.
<code>max.denominator</code>	An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point.
<code>...</code>	arguments passed to or from other methods.

### Details

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1 / (p_1 + 1 / (p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

### Value

A numeric object with the same attributes as `x` but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

### See Also

[fractions](#)

### Examples

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
```

---

renumerate

---

*Convert a Formula Transformed by 'denumerate'*

---

### Description

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

### Usage

```
renumerate(x)
```

### Arguments

`x`                      A formula, normally as modified by `denumerate`.

### Details

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

### Value

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

### See Also

`denumerate`

### Examples

```
denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
```

---

rlm

---

*Robust Fitting of Linear Models*

---

### Description

Fit a linear model by robust regression using an M estimator.

**Usage**

```

rlm(x, ...)

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
     method = c("M", "MM", "model.frame"),
     wt.method = c("inv.var", "case"),
     model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
     init = "ls", psi = psi.huber,
     scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
     method = c("M", "MM"), wt.method = c("inv.var", "case"),
     maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

```

**Arguments**

<code>formula</code>	a formula of the form $y \sim x_1 + x_2 + \dots$
<code>data</code>	data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>weights</code>	a vector of prior weights for each case.
<code>subset</code>	An index vector specifying the cases to be used in fitting.
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is <code>na.omit</code> , and can be changed by <code>options(na.action=)</code> .
<code>x</code>	a matrix or data frame containing the explanatory variables.
<code>y</code>	the response: a vector of length the number of rows of <code>x</code> .
<code>method</code>	currently either M-estimation or MM-estimation or (for the <code>formula</code> method only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-weight initialized by a specific S-estimator. See the ‘Details’ section.
<code>wt.method</code>	are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?
<code>model</code>	should the model frame be returned in the object?
<code>x.ret</code>	should the model matrix be returned in the object?
<code>y.ret</code>	should the response be returned in the object?
<code>contrasts</code>	optional contrast specifications: see <code>lm</code> .
<code>w</code>	(optional) initial down-weighting for each case.
<code>init</code>	(optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a <code>coef</code> component. Known methods are <code>"ls"</code> (the default) for an initial least-squares fit using weights <code>w*weights</code> , and <code>"lts"</code> for an unweighted least-trimmed squares fit with 200 samples.

<code>psi</code>	the <code>psi</code> function is specified by this argument. It must give (possibly by name) a function <code>g(x, ..., deriv)</code> that for <code>deriv=0</code> returns <code>psi(x)/x</code> and for <code>deriv=1</code> returns <code>psi'(x)</code> . Tuning constants will be passed in via <code>...</code>
<code>scale.est</code>	method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either "Huber" or "proposal 2").
<code>k2</code>	tuning constant used for Huber proposal 2 scale estimation.
<code>maxit</code>	the limit on the number of IWLS iterations.
<code>acc</code>	the accuracy for the stopping criterion.
<code>test.vec</code>	the stopping criterion is based on changes in this vector.
<code>...</code>	additional arguments to be passed to <code>rlm.default</code> or to the <code>psi</code> function.
<code>lqs.control</code>	An optional list of control values for <code>lqs</code> .
<code>u</code>	numeric vector of evaluation points.
<code>k, a, b, c</code>	tuning constants.
<code>deriv</code>	0 or 1: compute values of the <code>psi</code> function or of its first derivative.

## Details

Fitting is done by iterated re-weighted least squares (IWLS).

Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as `psi.huber`, `psi.hampel` and `psi.bisquare`. Huber's corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting `method = "MM"` selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with `k0 = 1.548`; this gives (for  $n \gg p$ ) breakdown point 0.5. The final estimator is an M-estimator with Tukey's biweight and fixed scale that will inherit this breakdown point provided `c > k0`; this is true for the default value of `c` that corresponds to 95% relative efficiency at the normal. Case weights are not supported for `method = "MM"`.

## Value

An object of class "rlm" inheriting from "lm". Note that the `df.residual` component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by "lm" methods.

The additional components not in an `lm` object are

<code>s</code>	the robust scale estimate used
<code>w</code>	the weights used in the IWLS process
<code>psi</code>	the <code>psi</code> function with parameters substituted
<code>conv</code>	the convergence criteria at each iteration
<code>converged</code>	did the IWLS converge?
<code>wresid</code>	a working residual, weighted for "inv.var" weights only.

---

rms.curv

*Relative Curvature Measures for Non-Linear Regression*

---

## Description

Calculates the root mean square parameter effects and intrinsic relative curvatures,  $c^\theta$  and  $c^t$ , for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

## Usage

```
rms.curv(obj)
```

## Arguments

`obj` Fitted model object of class "nls". The model must be fitted using the default algorithm.

## Details

The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the `pc` and `ic` components only, suitably annotated.

If either `pc` or `ic` exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

## Value

A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by  $\sqrt{F}$ , `ct` and `ci` for  $c^\theta$  and  $c^t$  (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.

## References

Bates, D. M, and Watts, D. G. (1988) *Nonlinear Regression Analysis and its Applications*. Wiley, New York.

## Examples

```
# The treated sample from the Puromycin data
mmcurve <- deriv3(~ Vm * conc/(K + conc), c("Vm", "K"),
                  function(Vm, K, conc) NULL)
Treated <- Puromycin[Puromycin$state == "treated", ]
(Purfit1 <- nls(rate ~ mmcurve(Vm, K, conc), data = Treated,
                start = list(Vm=200, K=0.1)))
rms.curv(Purfit1)
##Parameter effects: c^theta x sqrt(F) = 0.2121
##      Intrinsic: c^iota  x sqrt(F) = 0.092
```

---

rnegbin

---

*Simulate Negative Binomial Variates*

---

## Description

Function to generate random outcomes from a Negative Binomial distribution, with mean  $\mu$  and variance  $\mu + \mu^2/\theta$ .

## Usage

```
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

## Arguments

n	If a scalar, the number of sample values required. If a vector, <code>length(n)</code> is the number required and <code>n</code> is used as the mean vector if <code>mu</code> is not specified.
mu	The vector of means. Short vectors are recycled.
theta	Vector of values of the <code>theta</code> parameter. Short vectors are recycled.

## Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rnbinom` the index can be arbitrary.

## Value

Vector of random Negative Binomial variate values.

## Side Effects

Changes `.Random.seed` in the usual way.

**Examples**

```
# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
```

sammon

---

*Sammon's Non-Linear Mapping*

---

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,  
       magic = 0.2, tol = 1e-4)
```

**Arguments**

d	distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.
y	An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution. (If there are missing values in <code>d</code> , an initial configuration must be provided.) This must not have duplicates.
k	The dimension of the configuration.
niter	The maximum number of iterations.
trace	Logical for tracing optimization. Default <code>TRUE</code> .
magic	initial value of the step size constant in diagonal Newton method.
tol	Tolerance for stopping, in units of stress.

**Details**

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

**Value**

Two components:

points	A two-column vector of the fitted configuration.
stress	The final stress achieved.

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

snails

*Snail Mortality Data*

### Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

### Usage

```
snails
```

### Format

The data frame contains the following components:

Species snail species A (1) or B (2).

Exposure exposure in weeks.

Rel.Hum relative humidity (4 levels).

Temp temperature, in degrees Celsius (3 levels).

Deaths number of deaths.

N number of snails exposed.

---

 stepAIC

*Choose a model by AIC in a Stepwise Algorithm*

---

**Description**

Performs stepwise model selection by AIC.

**Usage**

```
stepAIC(object, scope, scale = 0,
        direction = c("both", "backward", "forward"),
        trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
        k = 2, ...)
```

**Arguments**

object an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.

scope defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.

scale	used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> and <code>aoV</code> models (see <code>extractAIC</code> for details).
direction	the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward".
trace	if positive, information is printed during the running of <code>stepAIC</code> . Larger values may give more information on the fitting process.
keep	a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything.
steps	the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
use.start	if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for <code>glm</code> (and other fits), but it can also slow them down. <b>Not used</b> in R.
k	the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.
...	any additional arguments to <code>extractAIC</code> . (None are currently used.)

### Details

The set of models searched is determined by the `scope` argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Where a conventional deviance exists (e.g. for `lm`, `aoV` and `glm` fits) this is quoted in the analysis of variance table: it is the *unscaled* deviance.

### Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aoV` and `survreg` fits, for example).

### Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

```

---

stormer

*The Stormer Viscometer Data*

---

## Description

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form  $\text{Time} = (B1 * \text{Viscosity}) / (\text{Weight} - B2) + E$  where  $B1$  and  $B2$  are unknown parameters to be estimated, and  $E$  is error.

## Usage

```
stormer
```

**Format**

The data frame contains the following components:

`Viscosity` viscosity of fluid.

`Wt` actuating weight.

`Time` time taken.

**Source**

summary.loglm*Summary Method Function for Objects of Class 'loglm'*

---

## Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using `loglm`.

## Usage

```
## S3 method for class 'loglm'  
summary(object, fitted = FALSE, ...)
```

## Arguments

<code>object</code>	a fitted <code>loglm</code> model object.
<code>fitted</code>	if <code>TRUE</code> return observed and expected frequencies in the result. Using <code>fitted = TRUE</code> may necessitate re-fitting the object.
<code>...</code>	arguments to be passed to or from other methods.

## Details

This function is a method for the generic function `summary()` for class `"loglm"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

## Value

a list is returned for use by `print.summary.loglm`. This has components

<code>formula</code>	the formula used to produce <code>object</code>
<code>tests</code>	the table of test statistics (likelihood ratio, Pearson) for the fit.
<code>oe</code>	if <code>fitted = TRUE</code> , an array of the observed and expected frequencies, otherwise <code>NULL</code> .

summary.negbin

*Summary Method Function for Objects of Class 'negbin'***Description**

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

**Usage**

```
## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

**Arguments**

<code>object</code>	fitted model object of class <code>negbin</code> inheriting from <code>glm</code> and <code>lm</code> . Typically the output of <code>glm.nb</code> .
<code>dispersion</code>	as for <code>summary.glm</code> , with a default of 1.
<code>correlation</code>	as for <code>summary.glm</code> .
<code>...</code>	arguments passed to or from other methods.

**Details**

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class `"negbin"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

**Value**

As for `summary.glm`; the additional lines of output are not included in the resultant object.

**Side Effects**

A summary table is produced as for `summary.glm`, with the additional information described above.

**References**

**Examples**

```
summary(glm.nb(Days ~ Eth*Age*Ln*Sex, quine, link = log))
```

summary.rlm

*Summary Method for Robust Linear Models***Description**

summary method for objects of class "rlm"

**Usage**

```
## S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

**Arguments**

object	the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class <code>rlm</code> , in the sense that the components returned by the <code>rlm</code> function will be available.
method	Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?
correlation	logical. Should correlations be computed (and printed)?
...	arguments passed to or from other methods.

**Details**

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.

**Value**

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the `summary` function.

correlation	The computed correlation coefficient matrix for the coefficients in the model.
cov.unscaled	The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.
sigma	The scale estimate.
stddev	A scale estimate used for the standard errors.
df	The number of degrees of freedom for the model and for residuals.
coefficients	A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.
terms	The terms object used in fitting this model.

**References**

```
summary(rlm(calls ~ year, data = phones, maxit = 50))
```

---

survey

*Student Survey Data*

---

**Description**

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

**Usage**

```
survey
```

**Format**

The components of the data frame are:

**Sex** The sex of the student. (Factor with levels "Male" and "Female".)

**Wr.Hnd** span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.

**NW.Hnd** span of non-writing hand.

**W.Hnd** writing hand of student. (Factor, with levels "Left" and "Right".)

**Fold** "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither".)

**Pulse** pulse rate of student (beats per minute).

**Clap** "Clap your hands! Which hand is on top?" (Factor, with levels "Right", "Left", "Neither".)

**Exer** how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None".)

**Smoke** how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never".)

**Height** height of the student in centimetres.

**M.I** whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial".)

**Age** age of the student in years.

**References**

synth.tr

*Synthetic Classification Problem***Description**

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

**Usage**

```
synth.tr
synth.te
```

**Format**

These data frames contains the following columns:

```
xs x-coordinate
ys y-coordinate
yc class, coded as 0 or 1.
```

**Source**

Ripley, B.D. (1994) Neural networks and related methods for classification (with discussion). *Journal of the Royal Statistical Society series B* **56**, 409–456.

Ripley, B.D. (1996) *Pattern Recognition and Neural Networks*. Cambridge: Cambridge University Press.

theta.md

*Estimate theta of the Negative Binomial***Description**

Given the estimated mean vector, estimate `theta` of the Negative Binomial Distribution.

**Usage**

```
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)

theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25,
         trace = FALSE)

theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```

**Arguments**

<code>y</code>	Vector of observed values from the Negative Binomial.
<code>mu</code>	Estimated mean vector.
<code>n</code>	Number of data points (defaults to the sum of <code>weights</code> )
<code>dfr</code>	Residual degrees of freedom (assuming <code>theta</code> known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.
<code>weights</code>	Case weights. If missing, taken as 1.
<code>limit</code>	Limit on the number of iterations.
<code>eps</code>	Tolerance to determine convergence.
<code>trace</code>	logical: should iteration progress be printed?

**Details**

`theta.md` estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

`theta.ml` uses maximum likelihood.

`theta.mm` calculates the moment estimator of `theta` by equating the Pearson chi-square  $\sum (y - \mu)^2 / (\mu + \mu^2 / \theta)$  to the residual degrees of freedom.

**Value**

The required estimate of `theta`, as a scalar. For `theta.ml`, the standard error is given as attribute "SE".

**See Also**

[glm.nb](#)

**Examples**

```
quine.nb <- glm.nb(Days ~ .^2, data = quine)
theta.md(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))
theta.ml(quine$Days, fitted(quine.nb))
theta.mm(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))

## weighted example
yeast <- data.frame(cbind(numbers = 0:5, fr = c(213, 128, 37, 18, 3, 1)))
fit <- glm.nb(numbers ~ 1, weights = fr, data = yeast)
summary(fit)
mu <- fitted(fit)
theta.md(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
theta.ml(yeast$numbers, mu, limit = 15, weights = yeast$fr)
theta.mm(yeast$numbers, mu, dfr = 399, weights = yeast$fr)
```

---

topo

*Spatial Topographic Data*

---

**Description**

The `topo` data frame has 52 rows and 3 columns, of topographic heights within a 310 feet square.

**Usage**

```
topo
```

**Format**

This data frame contains the following columns:

`x` x coordinates (units of 50 feet)

`y` y coordinates (units of 50 feet)

`z` heights (feet)

**Source**

Davis, J.C. (1973) *Statistics and Data Analysis in Geology*. Wiley.

Traffic

*Effect of Swedish Speed Limits on Accidents*

---

**Description**

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day `j` in 1962 was comparable to day `j` in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

**Usage**

```
Traffic
```

**Format**

This data frame contains the following columns:

`year` 1961 or 1962.

`day` of year.

`limit` was there a speed limit?

`y` traffic accident count for that day.

---

truehist	<i>Plot a Histogram</i>
----------	-------------------------

---

## Description

Creates a histogram on the current graphics device.

## Usage

```
truehist(data, nbins = "Scott", h, x0 = -h/1000,
          breaks, prob = TRUE, xlim = range(breaks),
          ymax = max(est), col = "cyan",
          xlab = deparse(substitute(data)), bty = "n", ...)
```

## Arguments

data	numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.
nbins	The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)
h	The bin width, a strictly positive number (takes precedence over nbins).
x0	Shift for the bins - the breaks are at $x0 + h * (... , -1, 0, 1, ...)$
breaks	The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
prob	If true (the default) plot a true histogram. The vertical axis has a <i>relative frequency density</i> scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.
xlim	The limits for the x-axis.
ymax	The upper limit for the y-axis.
col	The colour for the bar fill: the default is colour 5 in the default R palette.
xlab	label for the plot x-axis. By default, this will be the name of data.
bty	The box type for the plot - defaults to none.
...	additional arguments to <a href="#">rect</a> or <a href="#">plot</a> .

## Details

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

## Side Effects

A histogram is plotted on the current device.

 ucv

*Unbiased Cross-Validation for Bandwidth Selection*

---

## Description

Uses unbiased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

## Usage

```
ucv(x, nb = 1000, lower, upper)
```

## Arguments

`x` a numeric vector  
`nb` number of bins to use.  
`lower, upper` Range over which to minimize. The default is almost always satisfactory.

## Value

a bandwidth.

`UScereal`*Nutritional and Marketing Information on US Cereals*

---

**Description**

The `UScereal` data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

**Usage**

```
UScereal
```

**Format**

This data frame contains the following columns:

`mfr` Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.

`calories` number of calories in one portion.

`protein` grams of protein in one portion.

`fat` grams of fat in one portion.

`sodium` milligrams of sodium in one portion.

`fibre` grams of dietary fibre in one portion.

`carbo` grams of complex carbohydrates in one portion.

`sugars` grams of sugars in one portion.

`shelf` display shelf (1, 2, or 3, counting from the floor).

`potassium` grams of potassium.

`vitamins` vitamins and minerals (none, enriched, or 100%).

**Source**

The original data are available at <http://lib.stat.cmu.edu/datasets/1993.expo/>.

UScrime

*The Effect of Punishment Regimes on Crime Rates***Description**

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

**Usage**

UScrime

**Format**

This data frame contains the following columns:

M percentage of males aged 14–24.  
 So indicator variable for a Southern state.  
 Ed mean years of schooling.  
 Po1 police expenditure in 1960.  
 Po2 police expenditure in 1959.  
 LF labour force participation rate.  
 M.F number of males per 1000 females.  
 Pop state population.  
 NW number of non-whites per 1000 people.  
 U1 unemployment rate of urban males 14–24.  
 U2 unemployment rate of urban males 35–39.  
 GDP gross domestic product per head.  
 Ineq income inequality.  
 Prob probability of imprisonment.  
 Time average time served in state prisons.  
 y rate of crimes in a particular category per head of population.

 VA

*Veteran's Administration Lung Cancer Trial*

---

**Description**

Veteran's Administration lung cancer trial from Kalbfleisch & Prentice.

**Usage**

VA

**Format**

A data frame with columns:

`stime` survival or follow-up time in days.

`status` dead or censored.

`treat` treatment: standard or test.

`age` patient's age in years.

`Karn` Karnofsky score of patient's performance on a scale of 0 to 100.

`diag.time` times since diagnosis in months at entry to trial.

`cell` one of four cell types.

`prior` prior therapy?

 waders

*Counts of Waders at 15 Sites in South Africa*

---

**Description**

The `waders` data frame has 15 rows and 19 columns. The entries are counts of waders in summer.

**Usage**

`waders`

**Format**

This data frame contains the following columns (species)

S1 Oystercatcher  
 S2 White-fronted Plover  
 S3 Kitt Lutz's Plover  
 S4 Three-banded Plover  
 S5 Grey Plover  
 S6 Ringed Plover  
 S7 Bar-tailed Godwit  
 S8 Whimbrel  
 S9 Marsh Sandpiper  
 S10 Greenshank  
 S11 Common Sandpiper  
 S12 Turnstone  
 S13 Knot  
 S14 Sanderling  
 S15 Little Stint  
 S16 Curlew Sandpiper  
 S17 Ruff  
 S18 Avocet  
 S19 Black-winged Stilt

The rows are the sites:

A = Namibia North coast  
 B = Namibia North wetland  
 C = Namibia South coast  
 D = Namibia South wetland  
 E = Cape North coast  
 F = Cape North wetland  
 G = Cape West coast  
 H = Cape West wetland  
 I = Cape South coast  
 J = Cape South wetland  
 K = Cape East coast  
 L = Cape East wetland  
 M = Transkei coast  
 N = Natal coast  
 O = Natal wetland

```

whiteside

*House Insulation: Whiteside's Data***Description**

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

**Usage**

whiteside

**Format**

The whiteside data frame has 56 rows and 3 columns.:

Insul A factor, before or after insulation.

Temp Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas The weekly gas consumption in 1000s of cubic feet.

**Source**

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

Hand, D. J., Daly, F., McConway, K., Lunn, D. and Ostrowski, E. eds (1993) *A Handbook of Small Data Sets*. Chapman & Hall, p. 69.

**Examples**

```
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...) {
    panel.xyplot(x, y, ...)
    panel.lmline(x, y, ...)
  }, xlab = "Average external temperature (deg. C)",
  ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
  strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```

```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))
```

width.SJ

*Bandwidth Selection by Pilot Estimation of Derivatives***Description**

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))
```

**Arguments**

x	a numeric vector
nb	number of bins to use.
upper, lower	range over which to search for solution if method = "ste".
method	Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

**Value**

a bandwidth.

**References**

---

<code>write.matrix</code>	<i>Write a Matrix or Data Frame</i>
---------------------------	-------------------------------------

---

### Description

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

### Usage

```
write.matrix(x, file = "", sep = " ", blocksize)
```

### Arguments

<code>x</code>	matrix or data frame.
<code>file</code>	name of output file. The default ("") is the console.
<code>sep</code>	The separator between columns.
<code>blocksize</code>	If supplied and positive, the output is written in blocks of <code>blocksize</code> rows. Choose as large as possible consistent with the amount of memory available.

### Details

If `x` is a matrix, supplying `blocksize` is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If `x` is a data frame, the conversion to a matrix may negate the memory saving.

### Side Effects

A formatted file is produced, with column headings (if `x` has them) and columns of data.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

<code>wtloss</code>	<i>Weight Loss Data from an Obese Patient</i>
---------------------	---

---

### Description

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

### Usage

```
wtloss
```

**Format**

This data frame contains the following columns:

Days time in days since the start of the programme.

Weight weight in kilograms of the patient.

**Source**

Dr T. Davies, Adelaide.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),  
  data = wtloss, start = list(b0=90, b1=95, th=120))  
wtloss.fm  
plot(wtloss)  
with(wtloss, lines(Days, fitted(wtloss.fm)))
```

## Chapter 17

# The `Matrix` package

---

`abIndex-class`

*Class "abIndex" of Abstract Index Vectors*

---

### Description

The `"abIndex"` [class](#), short for “Abstract Index Vector”, is used for dealing with large index vectors more efficiently, than using integer (or [numeric](#)) vectors of the kind `2:1000000` or `c(0:1e5, 1000:1e6)`.

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (`packageDescription("Matrix")$Maintainer`).

### Objects from the Class

Objects can be created by calls of the form `new("abIndex", ...)`, but more easily and typically either by `as(x, "abIndex")` where `x` is an integer (valued) vector, or directly by `abIseq()` and combination `c(...)` of such.

### Slots

**kind:** a [character](#) string, one of `("int32", "double", "rleDiff")`, denoting the internal structure of the `abIndex` object.

**x:** Object of class `"numLike"`; is used (i.e., not of length 0) only iff the object is *not* compressed, i.e., currently exactly when `kind != "rleDiff"`.

**rleD:** object of class `"rleDiff"`, used for compression via [rle](#).

### Methods

**as.numeric, as.integer, as.vector** `signature(x = "abIndex"): ...`

**[** `signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...`

**coerce** `signature(from = "numeric", to = "abIndex"): ...`

**coerce** `signature(from = "abIndex", to = "numeric"): ...`

**coerce** `signature(from = "abIndex", to = "integer"): ...`

**length** `signature(x = "abIndex"): ...`

**Ops** signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**; see [Ops](#) for a list of these (S4) group methods.

**Ops** signature(e1 = "abIndex", e2 = "abIndex"):...

**Ops** signature(e1 = "abIndex", e2 = "numeric"):...

**Summary** signature(x = "abIndex"):...

**show** ("abIndex"): simple [show](#) method, building on `show(<rleDiff>)`.

**is.na** ("abIndex"): works analogously to regular vectors.

**is.finite, is.infinite** ("abIndex"): ditto.

### Note

This is currently experimental and not yet used for our own code. Please contact us (`packageDescription("Matrix")$Maintainer`), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package **ff**.

### See Also

[rle](#) (**base**) which is used here; [numeric](#)

### Examples

```
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex")) # note
ai # -> show() method

stopifnot(identical(-3:20,
                    as(abIseq1(-3,20), "vector")))
```

---

abIseq

*Sequence Generation of "abIndex", Abstract Index Vectors*

---

### Description

Generation of abstract index vectors, i.e., objects of class "[abIndex](#)".

`abIseq()` is designed to work entirely like [seq](#), but producing "[abIndex](#)" vectors.

`abIseq1()` is its basic building block, where `abIseq1(n,m)` corresponds to `n:m`.

`c(x, ...)` will return an "[abIndex](#)" vector, when `x` is one.

### Usage

```
abIseq1(from = 1, to = 1)
abIseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)),
        length.out = NULL, along.with = NULL)

## S3 method for class 'abIndex'
c(...)
```

**Arguments**

<code>from, to</code>	the starting and (maximal) end value of the sequence.
<code>by</code>	number: increment of the sequence.
<code>length.out</code>	desired length of the sequence. A non-negative number, which for <code>seq</code> and <code>seq.int</code> will be rounded up if fractional.
<code>along.with</code>	take the length from the length of this argument.
<code>...</code>	in general an arbitrary number of R objects; here, when the first is an <code>"abIndex"</code> vector, these arguments will be concatenated to a new <code>"abIndex"</code> object.

**Value**

An abstract index vector, i.e., object of class `"abIndex"`.

**See Also**

the class `abIndex` documentation; `rep2abI()` for another constructor; `rle` (**base**).

**Examples**

```
stopifnot(identical(-3:20,
                    as(abIseq1(-3,20), "vector")))

try( ## (arithmetic) not yet implemented
abIseq(1, 50, by = 3)
)
```

---

all-methods

---

*"Matrix" Methods for Functions all() and any()*

---

**Description**

The basic R functions `all` and `any` now have methods for `Matrix` objects and should behave as for `matrix` ones.

**Methods**

```
all signature(x = "Matrix", ..., na.rm = FALSE):...
any signature(x = "Matrix", ..., na.rm = FALSE):...
all signature(x = "ldenseMatrix", ..., na.rm = FALSE):...
all signature(x = "lsparseMatrix", ..., na.rm = FALSE):...
```

### Examples

```
M <- Matrix(1:12 + 0, 3, 4)
all(M >= 1) # TRUE
any(M < 0) # FALSE
MN <- M; MN[2,3] <- NA; MN
all(MN >= 0) # NA
any(MN < 0) # NA
any(MN < 0, na.rm = TRUE) # -> FALSE
```

---

all.equal-methods    *Matrix Package Methods for Function all.equal()*

---

### Description

Methods for function `all.equal()` (from R package **base**) are defined for all `Matrix` classes.

### Methods

```
target = "Matrix", current = "Matrix" \
target = "ANY", current = "Matrix" \
target = "Matrix", current = "ANY" these three methods are simply using
all.equal.numeric directly and work via as.vector().
```

There are more methods, notably also for `"sparseVector"`'s, see `showMethods("all.equal")`.

### Examples

```
showMethods("all.equal")

(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot( all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
                    lu.@L %*% lu.@U),
           with(ex, all.equal(as(P %*% A %*% Q, "CsparseMatrix"),
                               L %*% U)),
           with(ex, all.equal(as(A, "CsparseMatrix"),
                               t(P) %*% L %*% U %*% t(Q))))
```

---

atomicVector-class    *Virtual Class "atomicVector" of Atomic Vectors*

---

### Description

The `class` `"atomicVector"` is a *virtual* class containing all atomic vector classes of base R, as also implicitly defined via `is.atomic`.

### Objects from the Class

A virtual Class: No objects may be created from it.

## Methods

In the **Matrix** package, the "atomicVector" is used in signatures where typically “old-style” "matrix" objects can be used and can be substituted by simple vectors.

## Extends

The atomic classes "logical", "integer", "double", "numeric", "complex", "raw" and "character" are extended directly. Note that "numeric" already contains "integer" and "double", but we want all of them to be direct subclasses of "atomicVector".

## Author(s)

Martin Maechler

## See Also

`is.atomic`, `integer`, `numeric`, `complex`, etc.

## Examples

```
showClass("atomicVector")
```

---

band

---

*Extract bands of a matrix*

---

## Description

Returns a new matrix formed by extracting the lower triangle (`tril`) or the upper triangle (`triu`) or a general band relative to the diagonal (`band`), and setting other elements to zero. The general forms of these functions include integer arguments to specify how many diagonal bands above or below the main diagonal are not set to zero.

## Usage

```
band(x, k1, k2, ...)
tril(x, k = 0, ...)
triu(x, k = 0, ...)
```

## Arguments

<code>x</code>	a matrix-like object
<code>k, k1, k2</code>	integers specifying the diagonal bands that will not be set to zero. These are given relative to the main diagonal, which is <code>k=0</code> . A negative value of <code>k</code> indicates a diagonal below the main diagonal and a positive value indicates a diagonal above the main diagonal.
<code>...</code>	Optional arguments used by specific methods. (None used at present.)

## Value

An object of an appropriate matrix class. The class of the value of `tril` or `triu` inherits from `triangularMatrix` when appropriate. Note that the result is of class `sparseMatrix` only if `x` is.

**Methods**

**x = "CsparseMatrix"** method for compressed, sparse, column-oriented matrices.

**x = "TsparseMatrix"** method for sparse matrices in triplet format.

**x = "RsparseMatrix"** method for compressed, sparse, row-oriented matrices.

**x = "ddenseMatrix"** method for dense numeric matrices, including packed numeric matrices.

**See Also**

[bandSparse](#) for the *construction* of a banded sparse matrix directly from its non-zero diagonals.

**Examples**

```
## A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm)          # lower triangle
tril(mm, -1)      # strict lower triangle
triu(mm, 1)       # strict upper triangle
band(mm, -1, 2)   # general band
(m5 <- Matrix(rnorm(25), nc = 5))
tril(m5)          # lower triangle
tril(m5, -1)      # strict lower triangle
triu(m5, 1)       # strict upper triangle
band(m5, -1, 2)   # general band
(m65 <- Matrix(rnorm(30), nc = 5)) # not square
triu(m65)         # result in not dtrMatrix unless square
(sm5 <- crossprod(m65)) # symmetric
  band(sm5, -1, 1) # symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix") # often preferable
```

---

bandSparse

---

Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals

---

**Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

```
bandSparse(n, m = n, k, diagonals, symmetric = FALSE, giveCsparse = TRUE)
```

**Arguments**

**n, m** the matrix dimension  $(n, m) = (nrow, ncol)$ .

**k** integer vector of “diagonal numbers”, with identical meaning as in [band](#)(\*, k).

diagonals	optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class <code>nMatrix</code> . diagonals can also be $n' \times d$ matrix, where $d \leftarrow \text{length}(k)$ and $n' \geq \min(n, m)$ . In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals.
symmetric	logical; if true the result will be symmetric (inheriting from class <code>symmetricMatrix</code> ) and only the upper or lower triangle must be specified (via <code>k</code> and <code>diagonals</code> ).
giveCsparse	logical indicating if the result should be a <code>CsparseMatrix</code> or a <code>TsparseMatrix</code> . The default, TRUE is very often more efficient subsequently, but not always.

### Value

a sparse matrix (of class `CsparseMatrix`) of dimension  $n \times m$  with diagonal “bands” as specified.

### See Also

`band`, for extraction of matrix bands; `bdiag`, `diag`, `sparseMatrix`, `Matrix`.

### Examples

```
diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1, "dsCMatrix"))

## a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7, 9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

## If you want a pattern matrix, but with "sparse"-diagonals,
## you currently need to go via logical sparse:
lLis <- lapply(list(rpois(20, 2), rpois(20, 1), rpois(20, 3)) [c(1:3, 2:3, 3:2)],
              as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = lLis))
(s4. <- as(drop0(s4), "nsparseMatrix"))

n <- 1e4
bk <- c(0:5, 7, 11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
bLis <- as.data.frame(bMat)
B <- bandSparse(n, k = bk, diag = bLis)
Bs <- bandSparse(n, k = bk, diag = bLis, symmetric=TRUE)
B [1:15, 1:30]
Bs[1:15, 1:30]
## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
          identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE)))
```

bdiag

*Construct a Block Diagonal Matrix***Description**

Build a block diagonal matrix given several building block matrices.

**Usage**

```
bdiag(...)
.bdiag(lst)
```

**Arguments**

... individual matrices or a [list](#) of matrices.  
 lst non-empty [list](#) of matrices.

**Details**

For non-trivial argument list, `bdiag()` calls `.bdiag()`. The latter maybe useful to programmers

**Value**

A *sparse* matrix obtained by combining the arguments into a block diagonal matrix.

The value of `bdiag()` inherits from class [CsparseMatrix](#), whereas `.bdiag()` returns a [TsparseMatrix](#).

**Author(s)**

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates's faster implementation builds on [TsparseMatrix](#) objects.

**See Also**

[Diagonal](#) for constructing matrices of class [diagonalMatrix](#), or [kronecker](#) which also works for "Matrix" inheriting matrices.

[bandSparse](#) constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of `bdiag()` which return traditional matrices.

**Examples**

```
bdiag(matrix(1:4, 2), diag(3))
## combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))

m1st <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(m1st)
stopifnot(identical(bdiag(m1st),
                    bdiag(lapply(m1st, as.matrix))))
```

```
ml <- c(as(matrix((1:24)%% 11 == 0, 6, 4), "nMatrix"),
        rep(list(Diagonal(2, x=TRUE)), 3))
mln <- c(ml, Diagonal(x = 1:3))
stopifnot(is(bdiag(ml), "lsparseMatrix"),
          is(bdiag(mln), "dsparseMatrix") )
```

---

BunchKaufman-methods

### *Bunch-Kaufman Decomposition Methods*

---

## Description

The Bunch-Kaufman Decomposition of a square symmetric matrix  $A$  is  $A = PLDL'P'$  where  $P$  is a permutation matrix,  $L$  is *unit*-lower triangular and  $D$  is *block*-diagonal with blocks of dimension  $1 \times 1$  or  $2 \times 2$ .

## Usage

```
BunchKaufman(x, ...)
```

## Arguments

`x`                    a symmetric square matrix.  
`...`                potentially further arguments passed to methods.

## Value

an object of class `BunchKaufman`, which can also be used as a (triangular) matrix directly.

## Methods

Currently, only methods for **dense** numeric symmetric matrices are implemented.

`x = "dspMatrix"` uses Lapack routine `dsptf`,

`x = "dsyMatrix"` uses Lapack routine `dsytrf`, computing the Bunch-Kaufman decomposition.

## References

The original LAPACK source code, including documentation; <http://www.netlib.org/lapack/double/dsytrf.f> and <http://www.netlib.org/lapack/double/dsptf.f>

## See Also

The resulting class, `BunchKaufman`. Related decompositions are the LU, `lu`, and the Cholesky, `chol` (and for *sparse* matrices, `Cholesky`).

## Examples

```
data(CAex)
dim(CAex)
isSymmetric(CAex) # TRUE
CAs <- as(CAex, "symmetricMatrix")
if(FALSE) # no method defined yet for *sparse* :
  bk. <- BunchKaufman(CAs)
## does apply to *dense* symmetric matrices:
bkCA <- BunchKaufman(as(CAs, "denseMatrix"))
bkCA

image(bkCA) # shows how sparse it is, too
str(R.CA <- as(bkCA, "sparseMatrix"))
## an upper triangular 72x72 matrix with only 144 non-zero entries
```

---

CAex

---

*Albers' example Matrix with "Difficult" Eigen Factorization*

---

## Description

An example of a sparse matrix for which `eigen()` seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (<https://stat.ethz.ch/mailman/listinfo/r-help>), by Casper J Albers, Open University, UK.

## Usage

```
data(CAex)
```

## Format

This is a  $72 \times 72$  symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatrix`.

## Details

Historical note (2006-03-30): In earlier versions of R, `eigen(CAex)` fell into an infinite loop whereas `eigen(CAex, EISPACK=TRUE)` had been okay.

## Examples

```
data(CAex)
str(CAex) # of class "dgCMatrix"

image(CAex) # -> it's a simple band matrix with 5 bands
## and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
## i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
## and
stopifnot(class(sCA) == "dsCMatrix",
           as(sCA, "matrix") == as(CAex, "matrix"))
```

---

cBindVersions of 'cbind' and 'rbind' recursively built on cbind2/rbind2

---

## Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument `...`. For that reason, in the past S4 methods could easily be defined for binding together matrices inheriting from `Matrix`.

For that reason, `cbind2` and `rbind2` have been provided for binding together *two* matrices, and we have defined methods for these and the 'Matrix'-matrices.

Before R version 3.2.0 (April 2015), we have needed a substitute for *S4-enabled* versions of `cbind` and `rbind`, and provided `cBind` and `rBind` with identical syntax and semantic in order to bind together multiple matrices ("matrix" or "Matrix" and vectors. With R version 3.2.0 and newer, `cBind` and `rBind` are *deprecated* and produce a deprecation warning (via `.Deprecated`), and your code should start using `cbind()` and `rbind()` instead.

## Usage

```
cBind(..., deparse.level = 1)
rBind(..., deparse.level = 1)
```

## Arguments

`...` matrix-like R objects to be bound together, see `cbind` and `rbind`.  
`deparse.level` integer determining under which circumstances column and row names are built from the actual arguments' 'expression', see `cbind`.

## Details

The implementation of these is *recursive*, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

## Value

typically a 'matrix-like' object of a similar `class` as the first argument in `...`

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries than non-zero ones (as the default `sparse` in `Matrix()`).

## Author(s)

Martin Maechler

## See Also

`cbind2`, `cbind`, `Methods`.

**Examples**

```

(a <- matrix(c(2:1,1:2), 2,2))
D <- Diagonal(2)
if(getRversion() < "3.2.0") {
  M1 <- cbind(0, rBind(a, 7))
  print(M1) # remains traditional matrix

  M2 <- cBind(4, a, D, -1, D, 0) # a sparse Matrix
  print(M2)

} else { ## newer versions of R do not need cBind / rBind:

  M1 <- cbind(0, suppressWarnings(rBind(a, 7)))
  print(M1) # remains traditional matrix

  M2 <- suppressWarnings(cBind(4, a, D, -1, D, 0)) # a sparse Matrix
  print(M2)

  stopifnot(identical(M1, cbind(0, rbind(a, 7))),
             identical(M2, cbind(4, a, D, -1, D, 0)))
}## R >= 3.2.0

```

CHMfactor-class

*CHOLMOD-based Cholesky Factorizations***Description**

The virtual class "CHMfactor" is a class of CHOLMOD-based Cholesky factorizations of symmetric, sparse, compressed, column-oriented matrices. Such a factorization is simplicial (virtual class "CHMsimpl") or supernodal (virtual class "CHMsuper"). Objects that inherit from these classes are either numeric factorizations (classes "dCHMsimpl" and "dCHMsuper") or symbolic factorizations (classes "nCHMsimpl" and "nCHMsuper").

**Usage**

```

isLDL(x)

## S4 method for signature 'CHMfactor'
update(object, parent, mult = 0, ...)
.updateCHMfactor(object, parent, mult)

## and many more methods, notably,
##   solve(a, b, system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)
##   ----- see below

```

**Arguments**

<code>x, object, a</code>	a "CHMfactor" object (almost always the result of <code>Cholesky()</code> ).
<code>parent</code>	a "dsCMatrix" or "dgCMatrix" matrix object with the same nonzero pattern as the matrix that generated <code>object</code> . If <code>parent</code> is symmetric, of class "dsCMatrix", then <code>object</code> should be a decomposition of a matrix with the same nonzero pattern as <code>parent</code> . If <code>parent</code> is not symmetric then <code>object</code>

should be the decomposition of a matrix with the same nonzero pattern as `tcrossprod(parent)`.  
 Since Matrix version 1.0-8, other "sparseMatrix" matrices are coerced to `dsparseMatrix` and `CsparseMatrix` if needed.

**mult** a numeric scalar (default 0). `mult` times the identity matrix is (implicitly) added to `parent` or `tcrossprod(parent)` before updating the decomposition object.

**...** potentially further arguments to the methods.

### Objects from the Class

Objects can be created by calls of the form `new("dCHMsuper", ...)` but are more commonly created via `Cholesky()`, applied to `dsCMatrix` or `lsCMatrix` objects.

For an introduction, it may be helpful to look at the `expand()` method and examples below.

### Slots

of "CHMfactor" and all classes inheriting from it:

**perm**: An integer vector giving the 0-based permutation of the rows and columns chosen to reduce fill-in and for post-ordering.

**colcount**: Object of class "integer" ....

**type**: Object of class "integer" ....

Slots of the non virtual classes "[dl]CHM(super|simpl)":

**p**: Object of class "integer" of pointers, one for each column, to the initial (zero-based) index of elements in the column. Only present in classes that contain "CHMsimpl".

**i**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix. Only present in classes that contain "CHMsimpl".

**x**: For the "d\*" classes: "numeric" - the non-zero elements of the matrix.

### Methods

**isLDL** (`x`) returns a `logical` indicating if `x` is an  $LDL'$  decomposition or (when `FALSE`) an  $LL'$  one.

**coerce** `signature(from = "CHMfactor", to = "sparseMatrix")` (or equivalently, `to = "Matrix"` or `to = "triangularMatrix"`)

`as(*, "sparseMatrix")` returns the lower triangular factor  $L$  from the  $LL'$  form of the Cholesky factorization. Note that (currently) the factor from the  $LL'$  form is always returned, even if the "CHMfactor" object represents an  $LDL'$  decomposition. Furthermore, this is the factor after any fill-reducing permutation has been applied. See the `expand` method for obtaining both the permutation matrix,  $P$ , and the lower Cholesky factor,  $L$ .

**coerce** `signature(from = "CHMfactor", to = "pMatrix")` returns the permutation matrix  $P$ , representing the fill-reducing permutation used in the decomposition.

**expand** `signature(x = "CHMfactor")` returns a list with components  $P$ , the matrix representing the fill-reducing permutation, and  $L$ , the lower triangular Cholesky factor. The original positive-definite matrix  $A$  corresponds to the product  $A = P'LL'P$ . Because of fill-in during the decomposition the product may apparently have more non-zeros than the original matrix, even after applying `drop0` to it. However, the extra "non-zeros" should be very small in magnitude.

**image** signature( $x = \text{"CHMfactor"}$ ): Plot the image of the lower triangular factor,  $L$ , from the decomposition. This method is equivalent to `image(as(x, "sparseMatrix"))` so the comments in the above description of the `coerce` method apply here too.

**solve** signature( $a = \text{"CHMfactor"}, b = \text{"ddenseMatrix"}, \text{system} = *$ :

The `solve` methods for a "CHMfactor" object take an optional third argument `system` whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve  $Ax = b$  for  $x$  where  $A$  is the sparse, positive-definite matrix that was factored to produce  $a$ . Analogously, `system = "L"` returns the solution  $x$ , of  $Lx = b$ . Similarly, for all system codes **but** "P" and "Pt" where, e.g., `x <- solve(a, b, system="P")` is equivalent to `x <- P %*% b`.

See also [solve-methods](#).

**determinant** signature( $x = \text{"CHMfactor"}, \text{logarithm} = \text{"logical"}$ ) returns the determinant (or the logarithm of the determinant, if `logarithm = TRUE`, the default) of the factor  $L$  from the  $LL'$  decomposition (even if the decomposition represented by  $x$  is of the  $LDL'$  form (!)). This is the square root of the determinant (half the logarithm of the determinant when `logarithm = TRUE`) of the positive-definite matrix that was decomposed.

**update** signature( $\text{object} = \text{"CHMfactor"}, \text{parent}$ ). The `update` method requires an additional argument `parent`, which is *either* a "dsCMatrix" object, say  $A$ , (with the same structure of nonzeros as the matrix that was decomposed to produce `object`) or a general "dgCMatrix", say  $M$ , where  $A := MM'$  (`== tcrossprod(parent)`) is used for  $A$ . Further it provides an optional argument `mult`, a numeric scalar. This method updates the numeric values in `object` to the decomposition of  $A + mI$  where  $A$  is the matrix above (either the `parent` or  $MM'$ ) and  $m$  is the scalar `mult`. Because only the numeric values are updated this method should be faster than creating and decomposing  $A + mI$ . It is not uncommon to want, say, the determinant of  $A + mI$  for many different values of  $m$ . This method would be the preferred approach in such cases.

## See Also

[Cholesky](#), also for examples; class [dgCMatrix](#).

## Examples

```
## An example for the expand() method
n <- 1000; m <- 200; nnz <- 2000
set.seed(1)
M1 <- spMatrix(n, m,
               i = sample(n, nnz, replace = TRUE),
               j = sample(m, nnz, replace = TRUE),
               x = round(rnorm(nnz), 1))
XX <- crossprod(M1) ## = M1'M1 = M M' where M <- t(M1)
CX <- Cholesky(XX)
isLDL(CX)
str(CX) ## a "dCHMsimpl" object
r <- expand(CX)
L.P <- with(r, crossprod(L,P)) ## == L'P
PLLP <- crossprod(L.P) ## == (L'P)' L'P == P'LL'P = XX = M M'
b <- sample(m)
stopifnot(all.equal(PLLP, XX),
          all(as.vector(solve(CX, b, system="P" )) == r$P %*% b),
```

```

all(as.vector(solve(CX, b, system="Pt")) == t(r$P) %*% b) )

u1 <- update(CX, XX, mult=pi)
u2 <- update(CX, t(M1), mult=pi) # with the original M, where XX = M M'
stopifnot(all.equal(u1,u2, tol=1e-14))

## [ See help(Cholesky) for more examples ]
## -----

```

chol

*Choleski Decomposition - 'Matrix' S4 Generic and Methods*

## Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

## Usage

```

chol(x, ...)
## S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)
## S4 method for signature 'dsparseMatrix'
chol(x, pivot = FALSE, cache = TRUE, ...)

```

## Arguments

<code>x</code>	a (sparse or dense) square matrix, here inheriting from class <code>Matrix</code> ; if <code>x</code> is not positive definite, an error is signalled.
<code>pivot</code>	logical indicating if pivoting is to be used. Currently, this is <i>not</i> made use of for dense matrices.
<code>cache</code>	logical indicating if the result should be cached in <code>x@factors</code> ; note that this argument is experimental and only available for some sparse matrices.
<code>...</code>	potentially further arguments passed to methods.

## Details

Note that these Cholesky factorizations are typically *cached* with `x` currently, and these caches are available in `x@factors`, which may be useful for the sparse case when `pivot = TRUE`, where the permutation can be retrieved; see also the examples.

However, this should not be considered part of the API and made use of. Rather consider `Cholesky()` in such situations, since `chol(x, pivot=TRUE)` uses the same algorithm (but not the same return value!) as `Cholesky(x, LDL=FALSE)` and `chol(x)` corresponds to `Cholesky(x, perm=FALSE, LDL=FALSE)`.

## Value

a matrix of class `Cholesky`, i.e., upper triangular:  $R$  such that  $R'R = x$  (if `pivot=FALSE`) or  $P'R'RP = x$  (if `pivot=TRUE` and  $P$  is the corresponding permutation matrix).

## Methods

Use `showMethods(chol)` to see all; some are worth mentioning here:

- chol** signature(x = "dgeMatrix"): works via "dpoMatrix", see class `dpoMatrix`.
- chol** signature(x = "dpoMatrix"): Returns (and stores) the Cholesky decomposition of x, via LAPACK routines `dlacpy` and `dpotrf`.
- chol** signature(x = "dppMatrix"): Returns (and stores) the Cholesky decomposition via LAPACK routine `dpptrf`.
- chol** signature(x = "dsCMatrix", pivot = "logical"): Returns (and stores) the Cholesky decomposition of x. If `pivot` is true, the Approximate Minimal Degree (AMD) algorithm is used to create a reordering of the rows and columns of x so as to reduce fill-in.

## References

Timothy A. Davis (2006) *Direct Methods for Sparse Linear Systems*, SIAM Series "Fundamentals of Algorithms".

Tim Davis (1996), An approximate minimal degree ordering algorithm, *SIAM J. Matrix Analysis and Applications*, **17**, 4, 886–905.

## See Also

The default from **base**, `chol`; for more flexibility (but not returning a matrix!) `Cholesky`.

## Examples

```
showMethods(chol, inherited = FALSE) # show different methods

sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77))
(c2 <- chol(sy2))#-> "Cholesky" matrix
stopifnot(all.equal(c2, chol(as(sy2, "dpoMatrix")), tolerance= 1e-13))
str(c2)

## An example where chol() can't work
(sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7)))
try(chol(sy3)) # error, since it is not positive definite

## A sparse example --- exemplifying 'pivot'
(mm <- toeplitz(as(c(10, 0, 1, 0, 3), "sparseVector"))) # 5 x 5
(R <- chol(mm)) ## default: pivot = FALSE
R2 <- chol(mm, pivot=FALSE)
stopifnot( identical(R, R2), all.equal(crossprod(R), mm) )
(R. <- chol(mm, pivot=TRUE))# nice band structure,
## but of course crossprod(R.) is *NOT* equal to mm
## --> see Cholesky() and its examples, for the pivot structure & factorization
stopifnot(all.equal(sqrt(det(mm)), det(R)),
          all.equal(prod(diag(R)), det(R)),
          all.equal(prod(diag(R.)), det(R)))

## a second, even sparser example:
(M2 <- toeplitz(as(c(1,.5, rep(0,12), -.1), "sparseVector")))
c2 <- chol(M2)
C2 <- chol(M2, pivot=TRUE)
## For the experts, check the caching of the factorizations:
ff <- M2@factors[["spdCholesky"]]
```

```

FF <- M2@factors[["sPdCholesky"]]
L1 <- as(ff, "Matrix") # pivot=FALSE: no perm.
L2 <- as(FF, "Matrix"); P2 <- as(FF, "pMatrix")
stopifnot(identical(t(L1), c2),
           all.equal(t(L2), C2, tolerance=0), #-- why not identical()?
           all.equal(M2, tcrossprod(L1)),      # M = LL'
           all.equal(M2, crossprod(crossprod(L2, P2))) # M = P'L L'P
)

```

---

chol2inv-methods      *Inverse from Choleski or QR Decomposition – Matrix Methods*

---

## Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute  $(X'X)^{-1}$  from the ( $R$  part) of the QR decomposition of  $X$ .

Even more generally, given an upper triangular matrix  $R$ , compute  $(R'R)^{-1}$ .

## Methods

**x = "ANY"** the default method from **base**, see [chol2inv](#), for traditional matrices.

**x = "dtrMatrix"** method for the numeric triangular matrices, built on the same LAPACK DPOTRI function as the base method.

**x = "denseMatrix"** if  $x$  is coercable to a [triangularMatrix](#), call the "dtrMatrix" method above.

**x = "sparseMatrix"** if  $x$  is coercable to a [triangularMatrix](#), use [solve\(\)](#) currently.

## See Also

[chol](#) (for [Matrix](#) objects); further, [chol2inv](#) (from the **base** package), [solve](#).

## Examples

```

(M <- Matrix(cbind(1, 1:3, c(1,3,7))))
(cM <- chol(M)) # a "Cholesky" object, inheriting from "dtrMatrix"
chol2inv(cM) %*% M # the identity
stopifnot(all(chol2inv(cM) %*% M - Diagonal(nrow(M))) < 1e-10)

```

---

Cholesky      *Cholesky Decomposition of a Sparse Matrix*

---

## Description

Computes the Cholesky (aka “Choleski”) decomposition of a sparse, symmetric, positive-definite matrix. However, typically [chol\(\)](#) should rather be used unless you are interested in the different kinds of sparse Cholesky decompositions.

## Usage

```
Cholesky(A, perm = TRUE, LDL = !super, super = FALSE, Imult = 0, ...)
```

## Arguments

<code>A</code>	sparse symmetric matrix. No missing values or IEEE special values are allowed.
<code>perm</code>	logical scalar indicating if a fill-reducing permutation should be computed and applied to the rows and columns of <code>A</code> . Default is <code>TRUE</code> .
<code>LDL</code>	logical scalar indicating if the decomposition should be computed as <code>LDL'</code> where <code>L</code> is a unit lower triangular matrix. The alternative is <code>LL'</code> where <code>L</code> is lower triangular with arbitrary diagonal elements. Default is <code>TRUE</code> . Setting it to <code>NA</code> leaves the choice to a CHOLMOD-internal heuristic.
<code>super</code>	logical scalar indicating if a supernodal decomposition should be created. The alternative is a simplicial decomposition. Default is <code>FALSE</code> . Setting it to <code>NA</code> leaves the choice to a CHOLMOD-internal heuristic.
<code>Imult</code>	numeric scalar which defaults to zero. The matrix that is decomposed is $A+m*I$ where $m$ is the value of <code>Imult</code> and $I$ is the identity matrix of order <code>ncol(A)</code> .
<code>...</code>	further arguments passed to or from other methods.

## Details

This is a generic function with special methods for different types of matrices. Use `showMethods("Cholesky")` to list all the methods for the `Cholesky` generic.

The method for class `dsCMatrix` of sparse matrices — the only one available currently — is based on functions from the CHOLMOD library.

Again: If you just want the Cholesky decomposition of a matrix in a straightforward way, you should probably rather use `chol(.)`.

Note that if `perm=TRUE` (default), the decomposition is

$$A = P' \tilde{L} D \tilde{L}' P = P' L L' P,$$

where  $L$  can be extracted by `as(*, "Matrix")`,  $P$  by `as(*, "pMatrix")` and both by `expand(*)`, see the class `CHMfactor` documentation.

Note that consequently, you cannot easily get the “traditional” cholesky factor  $R$ , from this decomposition, as

$$R' R = A = P' L L' P = P' \tilde{R}' \tilde{R} P = (\tilde{R} P)' (\tilde{R} P),$$

but  $\tilde{R} P$  is *not* triangular even though  $\tilde{R}$  is.

## Value

an object inheriting from either `"CHMsuper"`, or `"CHMsimpl"`, depending on the `super` argument; both classes extend `"CHMfactor"` which extends `"MatrixFactorization"`.

In other words, the result of `Cholesky()` is *not* a matrix, and if you want one, you should probably rather use `chol(.)`, see Details.

**See Also**

Class definitions `CHMfactor` and `dsCMatrix` and function `expand`. Note the extra `solve(*, system = .)` options in `CHMfactor`.

Note that `chol()` returns matrices (inheriting from `"Matrix"`) whereas `Cholesky()` returns a `"CHMfactor"` object, and hence a typical user will rather use `chol(A)`.

**Examples**

```
data(KNex)
mtm <- with(KNex, crossprod(mm))
str(mtm@factors) # empty list()
(C1 <- Cholesky(mtm)) # uses show(<MatrixFactorization>)
str(mtm@factors) # 'SPDCholesky' (simpl)
(Cm <- Cholesky(mtm, super = TRUE))
c(C1 = isLDL(C1), Cm = isLDL(Cm))
str(mtm@factors) # 'SPDCholesky' *and* 'SPdCholesky'
str(cm1 <- as(C1, "sparseMatrix"))
str(cmat <- as(Cm, "sparseMatrix")) # hmm: super is *less* sparse here
cm1[1:20, 1:20]

b <- matrix(c(rep(0, 711), 1), nc = 1)
## solve(Cm, b) by default solves Ax = b, where A = Cm'Cm (= mtm)!
## hence, the identical() check *should* work, but fails on some GOTOblas:
x <- solve(Cm, b)
stopifnot(identical(x, solve(Cm, b, system = "A")),
           all.equal(x, solve(mtm, b)))

Cn <- Cholesky(mtm, perm = FALSE) # no permutation -- much worse:
sizes <- c(simple = object.size(C1),
           super = object.size(Cm),
           noPerm = object.size(Cn))
## simple is 100, super= 137, noPerm= 812 :
noquote(cbind(format(100 * sizes / sizes[1], digits=4)))

## Visualize the sparseness:
dq <- function(ch) paste('"' , ch, '"', sep="") ## dQuote(<UTF-8>) gives bad plots
image(mtm, main=paste("crossprod(mm) : Sparse", dq(class(mtm))))
image(cm1, main= paste("as(Cholesky(crossprod(mm)), \"sparseMatrix\") : ",
                      dq(class(cm1))))

## Smaller example, with same matrix as in help(chol) :
(mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)) # 5 x 5
(opts <- expand.grid(perm = c(TRUE,FALSE), LDL = c(TRUE,FALSE), super = c(FALSE,TRUE)))
rr <- lapply(seq_len(nrow(opts)), function(i)
             do.call(Cholesky, c(list(A = mm), opts[i,])))
nn <- do.call(expand.grid, c(attr(opts, "out.attr")$dimnames,
                             stringsAsFactors=FALSE, KEEP.OUT.ATTRS=FALSE))
names(rr) <- apply(nn, 1, function(r)
                  paste(sub("(=.) .*", "\\1", r), collapse=","))
str(rr, max=1)

str(re <- lapply(rr, expand), max=2) ## each has a 'P' and a 'L' matrix

R0 <- chol(mm, pivot=FALSE)
```

```

R1 <- chol(mm, pivot=TRUE )
stopifnot(all.equal(t(R1), re[[1]]$L),
          all.equal(t(R0), re[[2]]$L),
          identical(as(1:5, "pMatrix"), re[[2]]$P), # no pivoting
TRUE)

# Version of the underlying SuiteSparse library by Tim Davis :
.SuiteSparse_version()

```

Cholesky-class

*Cholesky and Bunch-Kaufman Decompositions*

## Description

The "Cholesky" class is the class of Cholesky decompositions of positive-semidefinite, real dense matrices. The "BunchKaufman" class is the class of Bunch-Kaufman decompositions of symmetric, real matrices. The "pCholesky" and "pBunchKaufman" classes are their *packed* storage versions.

## Objects from the Class

Objects can be created by calls of the form `new("Cholesky", ...)` or `new("BunchKaufman", ...)`, etc, or rather by calls of the form `chol(pm)` or `BunchKaufman(pm)` where `pm` inherits from the "dpoMatrix" or "dsyMatrix" class or as a side-effect of other functions applied to "dpoMatrix" objects (see `dpoMatrix`).

## Slots

A Cholesky decomposition extends class `MatrixFactorization` but is basically a triangular matrix extending the "dtrMatrix" class.

**uplo:** inherited from the "dtrMatrix" class.

**diag:** inherited from the "dtrMatrix" class.

**x:** inherited from the "dtrMatrix" class.

**Dim:** inherited from the "dtrMatrix" class.

**Dimnames:** inherited from the "dtrMatrix" class.

A Bunch-Kaufman decomposition also extends the "dtrMatrix" class and has a `perm` slot representing a permutation matrix. The packed versions extend the "dtpMatrix" class.

## Extends

Class "MatrixFactorization" and "dtrMatrix", directly. Class "dgeMatrix", by class "dtrMatrix". Class "Matrix", by class "dtrMatrix".

## Methods

Both these factorizations can *directly* be treated as (triangular) matrices, as they extend "dtrMatrix", see above. There are currently no further explicit methods defined with class "Cholesky" or "BunchKaufman" in the signature.

**Note**

1. Objects of class "Cholesky" typically stem from `chol(D)`, applied to a *dense* matrix *D*.  
On the other hand, the *function* `Cholesky(S)` applies to a *sparse* matrix *S*, and results in objects inheriting from class `CHMfactor`.
2. For traditional matrices *m*, `chol(m)` is a traditional matrix as well, triangular, but simply an  $n \times n$  numeric *matrix*. Hence, for compatibility, the "Cholesky" and "BunchKaufman" classes (and their "p\*" packed versions) also extend triangular Matrix classes (such as "dtrMatrix").  
Consequently, `determinant(R)` for `R <- chol(A)` returns the determinant of *R*, not of *A*. This is in contrast to class `CHMfactor` objects *C*, where `determinant(C)` gives the determinant of the *original* matrix *A*, for `C <- Cholesky(A)`, see also the determinant method documentation on the class `CHMfactor` page.

**See Also**

Classes `dtrMatrix`, `dpoMatrix`; function `chol`.

Function `Cholesky` resulting in class `CHMfactor` objects, *not* class "Cholesky" ones, see the section 'Note'.

**Examples**

```
(sm <- as(as(Matrix(diag(5) + 1), "dsyMatrix"), "dspMatrix"))
signif(csm <- chol(sm), 4)

(pm <- crossprod(Matrix(rnorm(18), nrow = 6, ncol = 3)))
(ch <- chol(pm))
if (toupper(ch@uplo) == "U") # which is TRUE
  crossprod(ch)
stopifnot(all.equal(as(crossprod(ch), "matrix"),
                     as(pm, "matrix"), tolerance=1e-14))
```

---

colSums

---

*Form Row and Column Sums and Means*

---

**Description**

Form row and column sums and means for objects, for `sparseMatrix` the result may optionally be sparse (`sparseVector`), too. Row or column names are kept respectively as for **base** matrices and `colSums` methods, when the result is `numeric` vector.

**Usage**

```
colSums(x, na.rm = FALSE, dims = 1, ...)
rowSums(x, na.rm = FALSE, dims = 1, ...)
colMeans(x, na.rm = FALSE, dims = 1, ...)
rowMeans(x, na.rm = FALSE, dims = 1, ...)

## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE,
        dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
```

```

rowSums(x, na.rm = FALSE,
        dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE,
         dims = 1, sparseResult = FALSE)
## S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE,
         dims = 1, sparseResult = FALSE)

```

### Arguments

<code>x</code>	a <i>Matrix</i> , i.e., inheriting from <i>Matrix</i> .
<code>na.rm</code>	logical. Should missing values (including NaN) be omitted from the calculations?
<code>dims</code>	completely ignored by the <i>Matrix</i> methods.
<code>...</code>	potentially further arguments, for method <-> generic compatibility.
<code>sparseResult</code>	logical indicating if the result should be sparse, i.e., inheriting from class <i>sparseVector</i> . Only applicable when <code>x</code> is inheriting from a <i>sparseMatrix</i> class.

### Value

returns a numeric vector if `sparseResult` is `FALSE` as per default. Otherwise, returns a *sparseVector*.

`dimnames(x)` are only kept (as `names(v)`) when the resulting `v` is *numeric*, since *sparseVectors* do not have names.

### See Also

*colSums* and the *sparseVector* classes.

### Examples

```

(M <- bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0' ; drop those:
MM <- drop0(MM)
length(MM@x) # 32
cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
          identical(cm, as.numeric(scm)))
rowSums(MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero
## Since we have no 'NA's, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
                    rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
          rowMeans(Diagonal(16)) == 1/16,
          colSums(Diagonal(7)) == 1)

## dimnames(x) --> names( <value> ) :

```

```

dimnames(M) <- list(paste0("r", 1:7), paste0("V",1:8))
M
colSums(M)
rowMeans(M)
## Assertions :
stopifnot(all.equal(colSums(M),
  setNames(c(1,1,6,6,6,6,3,2), colnames(M))),
  all.equal(rowMeans(M), structure(c(1,1,4,8,12,3,2) / 8,
    .Names = paste0("r", 1:7))))

```

---

compMatrix-class      *Class "compMatrix" of Composite (Factorizable) Matrices*

---

## Description

Virtual class of *composite* matrices; i.e., matrices that can be *factorized*, typically as a product of simpler matrices.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**factors:** Object of class "list" - a list of factorizations of the matrix. Note that this is typically empty, i.e., `list()`, initially and is *updated **automagically*** whenever a matrix factorization is computed.

**Dim, Dimnames:** inherited from the [Matrix](#) class, see there.

## Extends

Class "Matrix", directly.

## Methods

**dimnames<-** signature(x = "compMatrix", value = "list"): set the dimnames to a [list](#) of length 2, see [dimnames<-](#). The `factors` slot is currently reset to empty, as the factorization dimnames would have to be adapted, too.

## See Also

The matrix factorization classes "[MatrixFactorization](#)" and their generators, [lu\(\)](#), [qr\(\)](#), [chol\(\)](#) and [Cholesky\(\)](#), [BunchKaufman\(\)](#), [Schur\(\)](#).

---

condest	<i>Compute Approximate CONDition number and 1-Norm of (Large) Matrices</i>
---------	--

---

### Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix  $A$ . It works by apply a fast *randomized* approximation of the 1-norm, `norm(A, "1")`, through `onenormest()`.

### Usage

```
condest(A, t = min(n, 5), normA = norm(A, "1"),
        silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n,
           silent = FALSE, quiet = silent,
           iter.max = 10, eps = 4 * .Machine$double.eps)
```

### Arguments

A	a square matrix, optional for <code>onenormest()</code> , where instead of $A$ , $A.x$ and $At.x$ can be specified, see there.
t	number of columns to use in the iterations.
normA	number; (an estimate of) the 1-norm of $A$ , by default <code>norm(A, "1")</code> ; may be replaced by an estimate.
silent	logical indicating if warning and (by default) convergence messages should be displayed.
quiet	logical indicating if convergence messages should be displayed.
A.x, At.x	when $A$ is missing, these two must be given as functions which compute $A \% \% x$ , or $t(A) \% \% x$ , respectively.
n	<code>== nrow(A)</code> , only needed when $A$ is not specified.
iter.max	maximal number of iterations for the 1-norm estimator.
eps	the relative change that is deemed irrelevant.

### Details

`condest()` calls `lu(A)`, and subsequently `onenormest(A.x = , At.x = )` to compute an approximate norm of the *inverse* of  $A$ ,  $A^{-1}$ , in a way which keeps using sparse matrices efficiently when  $A$  is sparse.

Note that `onenormest()` uses random vectors and hence *both* functions' results are random, i.e., depend on the random seed, see, e.g., `set.seed()`.

### Value

Both functions return a `list`; `condest()` with components,

est	a number $> 0$ , the estimated (1-norm) condition number $\hat{\kappa}$ ; when $r := \text{rcond}(A)$ , $1/\hat{\kappa} \approx r$ .
-----	--

`v` the maximal  $Ax$  column, scaled to  $\text{norm}(v) = 1$ . Consequently,  $\text{norm}(Av) = \text{norm}(A)/\text{est}$ ; when `est` is large, `v` is an approximate null vector.

The function `onenormest()` returns a list with components,

`est` a number  $> 0$ , the estimated  $\text{norm}(A, "1")$ .  
`v` 0-1 integer vector length `n`, with an 1 at the index `j` with maximal column  $A[, j]$  in  $A$ .  
`w` numeric vector, the largest  $Ax$  found.  
`iter` the number of iterations used.

### Author(s)

This is based on octave's `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

### Examples

```
data(KNex)
mtm <- with(KNex, crossprod(mm))
system.time(ce <- condest(mtm))
sum(abs(ce$v)) ## || v ||_1 == 1
## Prove that || A v || = || A || / est (as ||v|| = 1):
stopifnot(all.equal(norm(mtm %*% ce$v),
                     norm(mtm) / ce$est))

## reciprocal
1 / ce$est
system.time(rc <- rcond(mtm)) # takes ca 3 x longer
rc
all.equal(rc, 1/ce$est) # TRUE -- the approximation was good

one <- onenormest(mtm)
str(one) ## est = 12.3
## the maximal column:
which(one$v == 1) # mostly 4, rarely 1, depending on random seed
```

---

CsparseMatrix-class

*Class "CsparseMatrix" of Sparse Matrices in Column-compressed Form*

---

## Description

The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("CsparseMatrix")` for its subclasses.

## Slots

**i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the *0-based* row numbers for each non-zero element in the matrix, i.e., *i* must be in `0:(nrow(.)-1)`.

**p:** integer vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. `.@p` is of length `ncol(.) + 1`, with `p[1] == 0` and `p[length(p)] == nnzero`, such that in fact, `diff(.@p)` are the number of non-zero elements for each column.

In other words, `m@p[1:ncol(m)]` contains the indices of those elements in `m@x` that are the first elements in the respective column of *m*.

**Dim, Dimnames:** inherited from the superclass, see the `sparseMatrix` class.

## Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

triu signature(x = "CsparseMatrix"): ...

```

### Note

All classes extending `CsparseMatrix` have a common validity (see `validObject`) check function. That function additionally checks the `i` slot for each column to contain increasing row numbers.

In earlier versions of **Matrix** ( $\leq 0.999375-16$ ), `validObject` automatically re-sorted the entries when necessary, and hence `new()` calls with somewhat permuted `i` and `x` slots worked, as `new(...)` (*with* slot arguments) automatically checks the validity.

Now, you have to use `sparseMatrix` to achieve the same functionality or know how to use `.validateCsparse()` to do so.

### See Also

`colSums`, `kronecker`, and other such methods with own help pages.

Further, the super class of `CsparseMatrix`, `sparseMatrix`, and, e.g., class `dgCMatrix` for the links to other classes.

### Examples

## The common validity check function (based on C code):
getValidity(getClass("CsparseMatrix"))

```

---

ddenseMatrix-class *Virtual Class "ddenseMatrix" of Numeric Dense Matrices*

---

### Description

This is the virtual class of all dense numeric (i.e., **double**, hence “*ddense*”) S4 matrices.

Its most important subclass is the `dgeMatrix` class.

### Extends

Class `"dMatrix"` directly; class `"Matrix"`, by the above.

### Slots

the same slots at its subclass `dgeMatrix`, see there.

## Methods

Most methods are implemented via `as(*, "dgeMatrix")` and are mainly used as “fallbacks” when the subclass doesn’t need its own specialized method.

Use `showMethods(class = "ddenseMatrix", where = "package:Matrix")` for an overview.

## See Also

The virtual classes `Matrix`, `dMatrix`, and `dsparseMatrix`.

## Examples

```
showClass("ddenseMatrix")

showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

ddiMatrix-class	<i>Class "ddiMatrix" of Diagonal Numeric Matrices</i>
-----------------	---

---

## Description

The class "ddiMatrix" of numerical diagonal matrices.

Note that diagonal matrices now extend `sparseMatrix`, whereas they did extend dense matrices earlier.

## Objects from the Class

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via `Diagonal`.

## Slots

**x:** numeric vector. For an  $n \times n$  matrix, the x slot is of length  $n$  or 0, depending on the diag slot:  
**diag:** "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.

**Dim,Dimnames:** matrix dimension and `dimnames`, see the `Matrix` class description.

## Extends

Class "`diagonalMatrix`", directly. Class "`dMatrix`", directly. Class "`sparseMatrix`", indirectly, see `showClass("ddiMatrix")`.

## Methods

`%%` signature(`x = "ddiMatrix", y = "ddiMatrix"`):...

## See Also

Class `diagonalMatrix` and function `Diagonal`.

**Examples**

```
(d2 <- Diagonal(x = c(10,1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> `fast' multiplication

chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "ddiMatrix"),
          all.equal(cd2%x, c(sqrt(10),1)))
```

---

denseMatrix-class    *Virtual Class "denseMatrix" of All Dense Matrices*

---

**Description**

This is the virtual class of all dense (S4) matrices. It is the direct superclass of [ddenseMatrix](#), [ldenseMatrix](#)

**Extends**

class "Matrix" directly.

**Slots**

exactly those of its superclass "[Matrix](#)".

**Methods**

Use [showMethods](#)(class = "denseMatrix", where = "package:Matrix") for an overview of methods.

Extraction ("[" ) methods, see [\[-methods](#).

**See Also**

[colSums](#), [kronecker](#), and other such methods with own help pages.

Its superclass [Matrix](#), and main subclasses, [ddenseMatrix](#) and [sparseMatrix](#).

**Examples**

```
showClass("denseMatrix")
```

---

 dgCMatrix-class      *Compressed, sparse, column-oriented numeric matrices*

---

## Description

The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the “*standard*” class for sparse numeric matrices in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgCMatrix", ...)`, more typically via `as(*, "CsparseMatrix")` or similar. Often however, more easily via `Matrix(*, sparse = TRUE)`, or most efficiently via `sparseMatrix()`.

## Slots

**x:** Object of class "numeric" - the non-zero elements of the matrix.

... all other slots are inherited from the superclass "`CsparseMatrix`".

## Methods

Matrix products (e.g., [crossprod-methods](#)), and (among other)

**coerce** signature(from = "matrix", to = "dgCMatrix")

**coerce** signature(from = "dgCMatrix", to = "matrix")

**coerce** signature(from = "dgCMatrix", to = "dgTMatrix")

**diag** signature(x = "dgCMatrix"): returns the diagonal of x

**dim** signature(x = "dgCMatrix"): returns the dimensions of x

**image** signature(x = "dgCMatrix"): plots an image of x using the [levelplot](#) function

**solve** signature(a = "dgCMatrix", b = "..."): see [solve-methods](#), notably the extra argument `sparse`.

**lu** signature(x = "dgCMatrix"): computes the LU decomposition of a square `dgCMatrix` object

## See Also

Classes [dsCMatrix](#), [dtCMatrix](#), [lu](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
```

---

dgcMatrix-class      *Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices*

---

## Description

A general numeric dense matrix in the S4 Matrix representation. `dgcMatrix` is the “standard” class for dense numeric matrices in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgeMatrix", ...)` or, more commonly, by coercion from the `Matrix` class (see [Matrix](#)) or by `Matrix(...)`.

## Slots

**x:** Object of class "numeric" - the numeric values contained in the matrix, in column-major order.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class [Matrix](#).

**factors:** Object of class "list" - a list of factorizations of the matrix.

## Methods

The are group methods (see, e.g., [Arith](#))

**Arith** signature(`e1` = "dgeMatrix", `e2` = "dgeMatrix"):...

**Arith** signature(`e1` = "dgeMatrix", `e2` = "numeric"):...

**Arith** signature(`e1` = "numeric", `e2` = "dgeMatrix"):...

**Math** signature(`x` = "dgeMatrix"):...

**Math2** signature(`x` = "dgeMatrix", `digits` = "numeric"):...

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several [solve](#) methods, and other matrix methods available:

**Schur** signature(`x` = "dgeMatrix", `vectors` = "logical"):...

**Schur** signature(`x` = "dgeMatrix", `vectors` = "missing"):...

**chol** signature(`x` = "dgeMatrix"): see [chol](#).

**coerce** signature(`from` = "dgeMatrix", `to` = "lgeMatrix"):...

**coerce** signature(`from` = "dgeMatrix", `to` = "matrix"):...

**coerce** signature(`from` = "matrix", `to` = "dgeMatrix"):...

**colMeans** signature(`x` = "dgeMatrix"): columnwise means (averages)

**colSums** signature(`x` = "dgeMatrix"): columnwise sums

**diag** signature(`x` = "dgeMatrix"):...

**dim** signature(`x` = "dgeMatrix"):...

**dimnames** signature(`x` = "dgeMatrix"):...

**eigen** signature(`x` = "dgeMatrix", `only.values` = "logical"):...

```

eigen signature(x = "dgeMatrix", only.values= "missing"):...
norm signature(x = "dgeMatrix", type = "character"):...
norm signature(x = "dgeMatrix", type = "missing"):...
rcond signature(x = "dgeMatrix", norm = "character")           or
      norm = "missing": the reciprocal condition number, rcond\(\).
rowMeans signature(x = "dgeMatrix"): rowwise means (averages)
rowSums signature(x = "dgeMatrix"): rowwise sums
t signature(x = "dgeMatrix"): matrix transpose

```

### See Also

Classes [Matrix](#), [dtrMatrix](#), and [dsyMatrix](#).

---

dgRMatrix-class      *Sparse Compressed, Row-oriented Numeric Matrices*

---

### Description

The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., [dgCMatrix](#), are preferred and better supported in the **Matrix** package.

### Objects from the Class

Objects can be created by calls of the form `new("dgRMatrix", ...)`.

### Slots

**j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.

**p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**x**: Object of class "numeric" - the non-zero elements of the matrix.

**Dim**: Object of class "integer" - the dimensions of the matrix.

### Methods

```

coerce signature(from = "matrix", to = "dgRMatrix")
coerce signature(from = "dgRMatrix", to = "matrix")
coerce signature(from = "dgRMatrix", to = "dgTMatrix")
diag signature(x = "dgRMatrix"): returns the diagonal of x
dim signature(x = "dgRMatrix"): returns the dimensions of x
image signature(x = "dgRMatrix"): plots an image of x using the levelplot function

```

**See Also**

the [RsparseMatrix](#) class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The [dgCMatrix](#) class (column compressed sparse) is really preferred.

---

dgTMatrix-class      *Sparse matrices in triplet form*

---

**Description**

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class [dgCMatrix](#).

**Objects from the Class**

Objects can be created by calls of the form `new("dgTMatrix", ...)`, but more typically via `as(*, "dgTMatrix")`, `spMatrix()`, or `sparseMatrix(*, giveCsparse=FALSE)`.

**Slots**

**i:** [integer](#) row indices of non-zero entries *in 0-base*, i.e., must be in `0:(nrow(.)-1)`.  
**j:** [integer](#) column indices of non-zero entries. Must be the same length as slot **i** and *0-based* as well, i.e., in `0:(ncol(.)-1)`.  
**x:** [numeric](#) vector - the (non-zero) entry at position `(i, j)`. Must be the same length as slot **i**. If an index pair occurs more than once, the corresponding values of slot **x** are added to form the element of the matrix.

**Dim:** Object of class "integer" of length 2 - the dimensions of the matrix.

**Methods**

**+** signature(e1 = "dgTMatrix", e2 = "dgTMatrix")

**coerce** signature(from = "dgTMatrix", to = "dgCMatrix")

**coerce** signature(from = "dgTMatrix", to = "dgeMatrix")

**coerce** signature(from = "dgTMatrix", to = "matrix"), and typically coercion methods for more specific signatures, we are not mentioning here.

Note that these are not guaranteed to continue to exist, but rather you should use calls like `as(x, "CsparseMatrix")`, `as(x, "generalMatrix")`, `as(x, "dMatrix")`, i.e. coercion to higher level virtual classes.

**coerce** signature(from = "matrix", to = "dgTMatrix"), (direct coercion from tradition matrix).

**image** signature(x = "dgTMatrix"): plots an image of **x** using the [levelplot](#) function

**t** signature(x = "dgTMatrix"): returns the transpose of **x**

**Note**

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to `dgCMatrix` objects.

Note that both `new(.)` and `spMatrix` constructors for `"dgTMatrix"` (and other `"TsparseMatrix"` classes) implicitly add  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs.

However this means that a matrix typically can be stored in more than one possible `"TsparseMatrix"` representations. Use `uniqTsparse()` in order to ensure uniqueness of the internal representation of such a matrix.

**See Also**

Class `dgCMatrix` or the superclasses `dsparseMatrix` and `TsparseMatrix`; `uniqTsparse`.

**Examples**

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT)],
                    m [lower.tri(m) ]))
mT[lower.tri(mT,diag=TRUE)] <- 0
mT

## Triplet representation with repeated (i,j) entries
## *adds* the corresponding x's:
T2 <- new("dgTMatrix",
          i = as.integer(c(1,1,0,3,3)),
          j = as.integer(c(2,2,4,0,0)), x=10*1:5, Dim=4:5)
str(T2) # contains (i,j,x) slots exactly as above, but
T2 ## has only three non-zero entries, as for repeated (i,j)'s,
    ## the corresponding x's are "implicitly" added
stopifnot(nnzero(T2) == 3)
```

---

Diagonal

---

*Create Diagonal Matrix Object*

---

**Description**

Create a diagonal matrix object, i.e., an object inheriting from `diagonalMatrix`.

**Usage**

```
Diagonal(n, x = NULL)

.symDiagonal(n, x = rep.int(1,n), uplo = "U")
.sparseDiagonal(n, x = 1, uplo = "U",
                shape = if(missing(cols)) "t" else "g",
                unitri, kind, cols = if(n) 0:(n - 1L) else integer(0))
```

**Arguments**

<code>n</code>	integer specifying the dimension of the (square) matrix. If missing, <code>length(x)</code> is used.
<code>x</code>	numeric or logical; if missing, a <i>unit</i> diagonal $n \times n$ matrix is created.
<code>uplo</code>	for <code>.symDiagonal</code> , the resulting sparse <code>symmetricMatrix</code> will have slot <code>uplo</code> set from this argument, either "U" or "L". Only rarely will it make sense to change this from the default.
<code>shape</code>	string of 1 character, one of <code>c("t", "s", "g")</code> , to choose a triangular, symmetric or general result matrix.
<code>unitri</code>	optional logical indicating if a triangular result should be “unit-triangular”, i.e., with <code>diag = "U"</code> slot, if possible. The default, <code>missing</code> , is the same as <code>TRUE</code> .
<code>kind</code>	string of 1 character, one of <code>c("d", "l", "n")</code> , to choose the storage mode of the result, from classes <code>dsparseMatrix</code> , <code>lsparseMatrix</code> , or <code>nsparseMatrix</code> , respectively.
<code>cols</code>	integer vector with values from <code>0:(n-1)</code> , denoting the <i>columns</i> to subselect conceptually, i.e., get the equivalent of <code>Diagonal(n, *)[, cols + 1]</code> .

**Value**

`Diagonal()` returns an object of class `ddiMatrix` or `ldiMatrix` (with “superclass” `diagonalMatrix`).

`.symDiagonal()` returns an object of class `dsCMatrix` or `lsCMatrix`, i.e., a *sparse symmetric* matrix. This can be more efficient than `Diagonal(n)` when the result is combined with further symmetric (sparse) matrices, however *not* for matrix multiplications where `Diagonal()` is clearly preferred.

`.sparseDiagonal()`, the workhorse of `.symDiagonal` returns a `CsparseMatrix` (the resulting class depending on `shape` and `kind`) representation of `Diagonal(n)`, or, when `cols` are specified, of `Diagonal(n)[, cols+1]`.

**Author(s)**

Martin Maechler

**See Also**

the generic function `diag` for *extraction* of the diagonal from a matrix works for all “Matrices”.

`bandSparse` constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals. `band(A)` returns a band matrix containing some sub-/super - diagonals of `A`.

`Matrix` for general matrix construction; further, class `diagonalMatrix`.

**Examples**

```
Diagonal(3)
Diagonal(x = 10^(3:1))
Diagonal(x = (1:4) >= 2) #-> "ldiMatrix"

## Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2, 3)
(M <- kronecker(Diagonal(3), M1))
```

```
(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10,6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
(I4 <- .sparseDiagonal(4, shape="t"))# now (2012-10) unitriangular
stopifnot(I4@diag == "U", all(I4 == diag(4)))
```

---

diagonalMatrix-class

*Class "diagonalMatrix" of Diagonal Matrices*

---

## Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**diag:** code"character" string, either "U" or "N", where "U" means ‘unit-diagonal’.

**Dim:** matrix dimension, and

**Dimnames:** the [dimnames](#), a [list](#), see the [Matrix](#) class description. Typically `list(NULL, NULL)` for diagonal matrices.

## Extends

Class "[sparseMatrix](#)", directly.

## Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

**coerce** signature(from = "matrix", to = "diagonalMatrix"):...

**coerce** signature(from = "Matrix", to = "diagonalMatrix"):...

**coerce** signature(from = "diagonalMatrix", to = "generalMatrix"):...

**coerce** signature(from = "diagonalMatrix", to = "triangularMatrix"):...

**coerce** signature(from = "diagonalMatrix", to = "nMatrix"):...

**coerce** signature(from = "diagonalMatrix", to = "matrix"):...

**coerce** signature(from = "diagonalMatrix", to = "sparseVector"):...

**t** signature(x = "diagonalMatrix"):...  
and many more methods

**solve** signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also [solve-methods](#).

**which** signature( $x = \text{"nMatrix"}$ ), semantically equivalent to **base** function `which(x, arr.ind)`.

**"Math"** signature( $x = \text{"diagonalMatrix"}$ ): all these group methods return a `"diagonalMatrix"`, apart from `cumsum()` etc which return a *vector* also for **base matrix**.

\* signature( $e1 = \text{"ddiMatrix"}$ ,  $e2 = \text{"denseMatrix"}$ ): arithmetic and other operators from the **Ops** group have a few dozen explicit method definitions, in order to keep the results *diagonal* in many cases, including the following:

/ signature( $e1 = \text{"ddiMatrix"}$ ,  $e2 = \text{"denseMatrix"}$ ): the result is from class `ddiMatrix` which is typically very desirable. Note that when  $e2$  contains off-diagonal zeros or **NA**s, we implicitly use  $0/x = 0$ , hence differing from traditional **R** arithmetic (where  $0/0 \mapsto \text{NaN}$ ), in order to preserve sparsity.

**summary** ( $\text{object} = \text{"diagonalMatrix"}$ ): Returns an object of **S3** class `"diagSummary"` which is the summary of the vector `object@x` plus a simple heading, and an appropriate `print` method.

### See Also

`Diagonal()` as constructor of these matrices, and `isDiagonal`. `ddiMatrix` and `ldiMatrix` are “actual” classes extending `"diagonalMatrix"`.

### Examples

```
I5 <- Diagonal(5)
D5 <- Diagonal(x = 10*(1:5))
## trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
           identical(tcrossprod(I5), I5),
           identical(crossprod(I5, D5), D5),
           identical(tcrossprod(D5, I5), D5),
           identical(solve(D5), solve(D5, I5)),
           all.equal(D5, solve(solve(D5)), tolerance = 1e-12)
)
solve(D5) # efficient as is diagonal

# an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5),
       cbind2(D5, I5))
```

---

diagU2N

---

*Transform Triangular Matrices from Unit Triangular to General Triangular and Back*

---

### Description

Transform a triangular matrix  $x$ , i.e., of class `"triangularMatrix"`, from (internally!) unit triangular (“unitriangular”) to “general” triangular (`diagU2N(x)`) or back (`diagN2U(x)`). Note that the latter, `diagN2U(x)`, also sets the diagonal to one in cases where `diag(x)` was not all one.

`.diagU2N(x)` assumes but does *not* check that  $x$  is a `triangularMatrix` with `diag` slot `"U"`, and should hence be used with care.

**Usage**

```
diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)

diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagU2N(x, cl, checkDense = FALSE)
```

**Arguments**

<code>x</code>	a <code>triangularMatrix</code> , often sparse.
<code>cl</code>	(optional, for speedup only:) class (definition) of <code>x</code> .
<code>checkDense</code>	logical indicating if dense (see <code>denseMatrix</code> ) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when <code>x</code> is dense.

**Details**

The concept of unit triangular matrices with a `diag` slot of "U" stems from LAPACK.

**Value**

a triangular matrix of the same `class` but with a different `diag` slot. For `diagU2N` (semantically) with identical entries as `x`, whereas in `diagN2U(x)`, the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

**Note**

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

**See Also**

"`triangularMatrix`", "`dtCMatrix`".

**Examples**

```
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7,7), k = 1))
(uT <- diagN2U(T)) # "unittriangular"
(t.u <- diagN2U(10*T)) # changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
           identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5
T <- diagN2U(as(T, "triangularMatrix"))
stopifnot(T@diag == "U")
dT <- as(T, "denseMatrix")
dt. <- diagN2U(dT)
dtU <- diagN2U(dT, checkDense=TRUE)
stopifnot(is(dtU, "denseMatrix"), is(dt., "sparseMatrix"),
           all(dT == dt.), all(dT == dtU),
           dt.@diag == "U", dtU@diag == "U")
```

dMatrix-class

(Virtual) Class "dMatrix" of "double" Matrices

## Description

The `dMatrix` class is a virtual class contained by all actual classes of numeric matrices in the **Matrix** package. Similarly, all the actual classes of logical matrices inherit from the `lMatrix` class.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding **Dim** element.

## Methods

There are (relatively simple) group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dMatrix", e2 = "dMatrix"):...

**Arith** signature(e1 = "dMatrix", e2 = "numeric"):...

**Arith** signature(e1 = "numeric", e2 = "dMatrix"):...

**Math** signature(x = "dMatrix"):...

**Math2** signature(x = "dMatrix", digits = "numeric"): this group contains [round\(\)](#) and [signif\(\)](#).

**Compare** signature(e1 = "numeric", e2 = "dMatrix"):...

**Compare** signature(e1 = "dMatrix", e2 = "numeric"):...

**Compare** signature(e1 = "dMatrix", e2 = "dMatrix"):...

**Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions [max\(\)](#), [min\(\)](#), [range\(\)](#), [prod\(\)](#), [sum\(\)](#), [any\(\)](#), and [all\(\)](#).

The following methods are also defined for all double matrices:

**coerce** signature(from = "dMatrix", to = "matrix"):...

**expm** signature(x = "dMatrix"): computes the “*Matrix Exponential*”, see [expm](#).

**zapsmall** signature(x = "dMatrix"):...

The following methods are defined for all logical matrices:

**which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the **base** function [which](#)(x, arr.ind) returns the indices of the **TRUE** entries in x; if `arr.ind` is true, as a 2-column matrix of row and column indices.

**See Also**

The nonzero-pattern matrix class `nMatrix`, which can be used to store non-NA logical matrices even more compactly.

The numeric matrix classes `dgeMatrix`, `dgCMatrix`, and `Matrix`.

`drop0(x, tol=1e-10)` is sometimes preferable to (and more efficient than) `zapsmall(x, digits=10)`.

**Examples**

```
showClass("dMatrix")

set.seed(101)
round(Matrix(rnorm(28), 4, 7), 2)
M <- Matrix(rlnorm(56, sd=10), 4, 14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

---

dpoMatrix-class	<i>Positive Semi-definite Dense Numeric Matrices</i>
-----------------	--

---

**Description**

The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in nonpacked storage. The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.

The "corMatrix" class extends "dpoMatrix" with a slot `sd`.

**Objects from the Class**

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.

**Slots**

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

**Dimnames:** inherited from class "Matrix"

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**sd:** (for "corMatrix") a numeric vector of length `n` containing the (original)  $\sqrt{\text{var}(\cdot)}$  entries which allow reconstruction of a covariance matrix from the correlation matrix.

**Extends**

Class "dsyMatrix", directly.

Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

## Methods

**chol** signature(`x = "dpoMatrix"`): Returns (and stores) the Cholesky decomposition of `x`, see [chol](#).

**determinant** signature(`x = "dpoMatrix"`): Returns the [determinant](#) of `x`, via `chol(x)`, see above.

**rcond** signature(`x = "dpoMatrix"`, `norm = "character"`): Returns (and stores) the reciprocal of the condition number of `x`. The `norm` can be `"O"` for the one-norm (the default) or `"I"` for the infinity-norm. For symmetric matrices the result does not depend on the norm.

**solve** signature(`a = "dpoMatrix"`, `b = "..."`), and

**solve** signature(`a = "dppMatrix"`, `b = "..."`) work via the Cholesky composition, see also the Matrix [solve-methods](#).

**Arith** signature(`e1 = "dpoMatrix"`, `e2 = "numeric"`) (and quite a few other signatures): The result of (“elementwise” defined) arithmetic operations is typically *not* positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with `positive length(.) == 1` numbers (or [logicals](#)).

## See Also

Classes [dsyMatrix](#) and [dgeMatrix](#); further, [Matrix](#), [rcond](#), [chol](#), [solve](#), [crossprod](#).

## Examples

```
h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is ``integer``
solve(h6)
str(hp6 <- as(h6, "dppMatrix"))

### Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(h6 * 27720, round(27720 * h6), tolerance = 1e-14),
          all.equal(ch6@sd^(-2), 2*(1:6)-1, tolerance= 1e-12))
chch <- chol(ch6)
stopifnot(identical(chch, ch6@factors$Cholesky),
          all(abs(crossprod(chch) - ch6) < 1e-10))
```

---

drop0

*Drop "Explicit Zeroes" from a Sparse Matrix*

---

## Description

Returns a sparse matrix with no “explicit zeroes”, i.e., all zero or `FALSE` entries are dropped from the explicitly indexed matrix entries.

## Usage

```
drop0(x, tol = 0, is.Csparse = NA)
```

**Arguments**

<code>x</code>	a Matrix, typically sparse, i.e., inheriting from <code>sparseMatrix</code> .
<code>tol</code>	non-negative number to be used as tolerance for checking if an entry $x_{i,j}$ should be considered to be zero.
<code>is.Csparse</code>	logical indicating prior knowledge about the “Cspareness” of <code>x</code> . This exists for possible speedup reasons only.

**Value**

a Matrix like `x` but with no explicit zeros, i.e., `!any(x@x == 0)`, always inheriting from `CsparseMatrix`.

**Note**

When a sparse matrix is the result of matrix multiplications, you may want to consider combining `drop0()` with `zapsmall()`, see the example.

**See Also**

`spMatrix`, class `sparseMatrix`; `nnzero`

**Examples**

```
m <- spMatrix(10,20, i= 1:8, j=2:9, x = c(0:2,3:-1))
m
drop0(m)

## A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
        x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
        i = c(0L,2L,4L, 1L, 3L,2L,4L, 3L, 4L),
        p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5,t5), t5))
IT <- solve(TT)
I. <- TT %*% IT ; nnzero(I.) # 697 ( = 625 + 72 )
I.0 <- drop0(zapsmall(I.))
## which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.0 == Diagonal(625)),
          nnzero(I..) == 625)
```

---

dsCMatrix-class

*Numeric Symmetric Sparse (column compressed) Matrices*

---

**Description**

The `dsCMatrix` class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The `dsTMatrix` class is the class of symmetric, sparse numeric matrices in triplet format.

## Objects from the Class

Objects can be created by calls of the form `new("dsCMatrix", ...)` or `new("dsTMatrix", ...)`, or automatically via e.g., `as(*, "symmetricMatrix")`, or (for `dsCMatrix`) also from `Matrix(.)`.

Creation “from scratch” most efficiently happens via `sparseMatrix(*, symmetric=TRUE)`.

## Slots

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.

**i:** Object of class "integer" of length `nnZ` (*half* number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.

**p:** (only in class "dsCMatrix":) an `integer` vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

**j:** (only in class "dsTMatrix":) Object of class "integer" of length `nnZ` (as `i`). These are the column numbers for each non-zero element in the lower triangle of the matrix.

**x:** Object of class "numeric" of length `nnZ` – the non-zero elements of the matrix (to be duplicated for full matrix).

**factors:** Object of class "list" - a list of factorizations of the matrix.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

## Extends

Both classes extend classes `symmetricMatrix` `dsparseMatrix` directly; `dsCMatrix` further directly extends `CsparseMatrix`, where `dsTMatrix` does `TsparseMatrix`.

## Methods

**solve** signature(`a` = "dsCMatrix", `b` = "..."): `x <- solve(a,b)` solves  $Ax = b$  for  $x$ ; see `solve-methods`.

**chol** signature(`x` = "dsCMatrix", `pivot` = "logical"): Returns (and stores) the Cholesky decomposition of `x`, see `chol`.

**Cholesky** signature(`A` = "dsCMatrix", ...): Computes more flexibly Cholesky decompositions, see `Cholesky`.

**determinant** signature(`x` = "dsCMatrix", `logarithm` = "missing"): Evaluate the determinant of `x` on the logarithm scale. This creates and stores the Cholesky factorization.

**determinant** signature(`x` = "dsCMatrix", `logarithm` = "logical"): Evaluate the determinant of `x` on the logarithm scale or not, according to the `logarithm` argument. This creates and stores the Cholesky factorization.

**t** signature(`x` = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the `uplo` slot is swapped, and the row and column indices are interchanged.

**t** signature(`x` = "dsTMatrix"): Transpose. The `uplo` slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

**coerce** signature(`from` = "dsCMatrix", `to` = "dgTMatrix")

**coerce** signature(`from` = "dsCMatrix", `to` = "dgeMatrix")

**coerce** signature(`from` = "dsCMatrix", `to` = "matrix")

```

coerce signature(from = "dsTMatrix", to = "dgeMatrix")
coerce signature(from = "dsTMatrix", to = "dsCMatrix")
coerce signature(from = "dsTMatrix", to = "dsyMatrix")
coerce signature(from = "dsTMatrix", to = "matrix")

```

### See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#) and those mentioned above.

### Examples

```

mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mm # automatically dsCMatrix
str(mm)

## how would we go from a manually constructed Tsparse* :
mT <- as(mm, "dgTMatrix")

## Either
(symM <- as(mT, "symmetricMatrix"))# dsT
(symC <- as(symM, "CsparseMatrix"))# dsC
## or
sC <- Matrix(mT, sparse=TRUE, forceCheck=TRUE)

sym2 <- as(symC, "TsparseMatrix")
## --> the same as 'symM', a "dsTMatrix"

```

---

`dsparseMatrix-class`

*Virtual Class "dsparseMatrix" of Numeric Sparse Matrices*

---

### Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

### Slots

**Dim:** the matrix dimension, see class "[Matrix](#)".

**Dimnames:** see the "Matrix" class.

**x:** a [numeric](#) vector containing the (non-zero) matrix entries.

### Extends

Class "dMatrix" and "sparseMatrix", directly.

Class "Matrix", by the above classes.

### See Also

the documentation of the (non virtual) sub classes, see `showClass("dsparseMatrix")`; in particular, [dgTMatrix](#), [dgCMatrix](#), and [dgRMatrix](#).

**Examples**

```
showClass("dsparseMatrix")
```

---

dsRMatrix-class	<i>Symmetric Sparse Compressed Row Matrices</i>
-----------------	---

---

**Description**

The `dsRMatrix` class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Objects from the Class**

These `"..RMatrix"` classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMatrix", ...)`.

**Slots**

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.

**j:** Object of class `"integer"` of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class `"integer"` of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**factors:** Object of class `"list"` - a list of factorizations of the matrix.

**x:** Object of class `"numeric"` - the non-zero elements of the matrix.

**Dim:** Object of class `"integer"` - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** List of length two, see [Matrix](#).

**Extends**

Classes [RsparseMatrix](#), [dsparseMatrix](#) and [symmetricMatrix](#), directly.

Class `"dMatrix"`, by class `"dsparseMatrix"`, class `"sparseMatrix"`, by class `"dsparseMatrix"` or `"RsparseMatrix"`; class `"compMatrix"` by class `"symmetricMatrix"` and of course, class `"Matrix"`.

**Methods**

**forceSymmetric** signature(`x = "dsRMatrix"`, `uplo = "missing"`): a trivial method just returning `x`

**forceSymmetric** signature(`x = "dsRMatrix"`, `uplo = "character"`): if `uplo == x@uplo`, this trivially returns `x`; otherwise `t(x)`.

**coerce** signature(`from = "dsCMatrix"`, `to = "dsRMatrix"`)

**See Also**

the classes [dgCMatrix](#), [dgTMatrix](#), and [dgeMatrix](#).

**Examples**

```

(m0 <- new("dsRMatrix"))
m2 <- new("dsRMatrix", Dim = c(2L,2L),
          x = c(3,1), j = c(1L,1L), p = 0:2)
m2
stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)
str(m2)
(ds2 <- forceSymmetric(diag(2))) # dsy*
dR <- as(ds2, "RsparseMatrix")
dR # dsRMatrix

```

---

dsyMatrix-class	<i>Symmetric Dense Numeric Matrices</i>
-----------------	---

---

**Description**

The "dsyMatrix" class is the class of symmetric, dense matrices in non-packed storage and "dspMatrix" is the class of symmetric dense matrices in packed storage. Only the upper triangle or the lower triangle is stored.

**Objects from the Class**

Objects can be created by calls of the form `new("dsyMatrix", ...)`.

**Slots**

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#).

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

"dsyMatrix" extends class "dgeMatrix", directly, whereas

"dspMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use `showClass("dsyMatrix")`, e.g., for details.

**Methods**

**coerce** signature(from = "ddenseMatrix", to = "dgeMatrix")

**coerce** signature(from = "dspMatrix", to = "matrix")

**coerce** signature(from = "dsyMatrix", to = "matrix")

**coerce** signature(from = "dsyMatrix", to = "dspMatrix")

**coerce** signature(from = "dspMatrix", to = "dsyMatrix")

**norm** signature(x = "dspMatrix", type = "character"), or  
 x = "dsyMatrix" or type = "missing": Computes the matrix norm of the  
 desired type, see, [norm](#).

**rcond** signature(x = "dspMatrix", type = "character"), or  
 x = "dsyMatrix" or type = "missing": Computes the reciprocal condition  
 number, [rcond\(\)](#).

**solve** signature(a = "dspMatrix", b = "..."), and

**solve** signature(a = "dsyMatrix", b = "..."):  $x \leftarrow \text{solve}(a, b)$  solves  
 $Ax = b$  for  $x$ ; see [solve-methods](#).

**t** signature(x = "dsyMatrix"): Transpose; swaps from upper triangular to lower trian-  
 gular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric  
 matrices.

### See Also

Classes [dgeMatrix](#) and [Matrix](#); [solve](#), [norm](#), [rcond](#), [t](#)

### Examples

```
## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

## Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite
```

---

dtCMatrix-class	<i>Triangular, (compressed) sparse column matrices</i>
-----------------	--

---

### Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.

### Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via [Matrix\(\)](#) or coercion such as `as(x, "triangularMatrix")`, or `as(x, "dtCMatrix")`.

## Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- p:** (only present in "dtCMatrix":) an [integer](#) vector for providing pointers, one for each column, see the detailed description in [CsparseMatrix](#).
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the [dtTMatrix](#) class.)
- x:** Object of class "numeric" - the non-zero elements of the matrix.
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

## Methods

```

coerce signature(from = "dtCMatrix", to = "dgTMatrix")
coerce signature(from = "dtCMatrix", to = "dgeMatrix")
coerce signature(from = "dtTMatrix", to = "dgeMatrix")
coerce signature(from = "dtTMatrix", to = "dtrMatrix")
coerce signature(from = "dtTMatrix", to = "matrix")
solve signature(a = "dtCMatrix", b = "..."): sparse triangular solve (aka
  "backsolve" or "forwardsolve"), see solve-methods.
t signature(x = "dtCMatrix"): returns the transpose of x
t signature(x = "dtTMatrix"): returns the transpose of x

```

## See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#), and [dtrMatrix](#).

## Examples

```

showClass("dtCMatrix")

showClass("dtTMatrix")
t1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
t1
## from 0-diagonal to unit-diagonal {low-level step}:
tu <- t1 ; tu@diag <- "U"
tu
(cu <- as(tu, "dtCMatrix"))
str(cu)# only two entries in @i and @x
stopifnot(cu@i == 1:0,

```

```

all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu))

t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)

## 2nd example
U5 <- new("dtCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
          x = rep(1, 5), diag = "U")
U5
(iu <- solve(U5)) # contains one '0'
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions

I5 <- iu %**% U5 # should equal the identity matrix
i5 <- iu2 %**% U5
m53 <- matrix(1:15, 5,3, dimnames=list(NULL,letters[1:3]))
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
stopifnot(
  all.equal(Diagonal(5), asDiag(I5), tolerance=1e-14) ,
  all.equal(Diagonal(5), asDiag(i5), tolerance=1e-14) ,
  identical(list(NULL, dimnames(m53)[[2]]), dimnames(solve(U5, m53)))
)

```

---

dtpMatrix-class      *Packed Triangular Dense Matrices - "dtpMatrix"*

---

## Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

## Objects from the Class

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension  $d \times d$ , `length(x)` is of length  $d(d+1)/2$  (also when `diag == "U"!`).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

## Methods

```
%% signature(x = "dtpMatrix", y = "dgeMatrix"):      Ma-
  trix multiplication; ditto for several other signature combinations, see
  showMethods("%*%", class = "dtpMatrix").

coerce signature(from = "dtpMatrix", to = "dtrMatrix")

coerce signature(from = "dtpMatrix", to = "matrix")

determinant signature(x = "dtpMatrix", logarithm = "logical"): the
  determinant(x) trivially is prod(diag(x)), but computed on log scale to prevent
  over- and underflow.

diag signature(x = "dtpMatrix"): ...

norm signature(x = "dtpMatrix", type = "character"): ...

rcond signature(x = "dtpMatrix", norm = "character"): ...

solve signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve
  or forwardsolve, see solve-methods.

t signature(x = "dtpMatrix"): t(x) remains a "dtpMatrix", lower triangular if x
  is upper triangular, and vice versa.
```

## See Also

Class [dtrMatrix](#)

## Examples

```
showClass("dtrMatrix")

example("dtrMatrix-class", echo=FALSE)
(p1 <- as(T2, "dtpMatrix"))
str(p1)
(pp <- as(T, "dtpMatrix"))
ip1 <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3,
  p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo,
  identical(t(pp), p1), identical(t(p1), pp),
  all((l.d <- p1 - T2) == 0), is(l.d, "dtpMatrix"),
  all((u.d <- pp - T) == 0), is(u.d, "dtpMatrix"),
  l.d@uplo == T2@uplo, u.d@uplo == T@uplo,
  identical(t(ip1), solve(pp)), is(ip1, "dtpMatrix"),
  all.equal(as(solve(p1,p1), "diagonalMatrix"), Diagonal(2)))
```

---

dtRMatrix-class      *Triangular Sparse Compressed Row Matrices*

---

## Description

The `dtRMatrix` class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing columnnd order.

## Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**j:** Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the `dsRMatrix` class.)

**x:** Object of class "numeric" - the non-zero elements of the matrix.

**Dim:** The dimension (a length-2 "integer")

**Dimnames:** corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

## Methods

No methods currently with class "dsRMatrix" in the signature.

## See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#)

## Examples

```
(m0 <- new("dtRMatrix"))
(m2 <- new("dtRMatrix", Dim = c(2L,2L),
           x = c(5, 1:2), p = c(0L,2:3), j= c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatrix
```

---

dtrMatrix-class      *Triangular, dense, numeric matrices*

---

### Description

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage.

### Objects from the Class

Objects can be created by calls of the form `new("dtrMatrix", ...)`.

### Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

### Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

### Methods

Among others (such as matrix products, e.g. [?crossprod-methods](#)),

**coerce** signature(from = "dgeMatrix", to = "dtrMatrix")

**coerce** signature(from = "dtrMatrix", to = "matrix")

**coerce** signature(from = "dtrMatrix", to = "ltrMatrix")

**coerce** signature(from = "dtrMatrix", to = "matrix")

**coerce** signature(from = "matrix", to = "dtrMatrix")

**norm** signature(x = "dtrMatrix", type = "character")

**rcond** signature(x = "dtrMatrix", norm = "character")

**solve** signature(a = "dtrMatrix", b = "...") efficiently use a "forwardsolve" or "backsolve" for a lower or upper triangular matrix, respectively, see also [solve-methods](#).

**+, -, \*, ..., ==, >=, ...** all the [Ops](#) group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.

### See Also

Classes [ddenseMatrix](#), [dtpMatrix](#), [triangularMatrix](#)

**Examples**

```
(m <- rbind(2:3, 0:-1))
(M <- as(m, "dgeMatrix"))

(T <- as(M, "dtrMatrix")) ## upper triangular is default
(T2 <- as(t(M), "dtrMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))
```

expand

*Expand a Decomposition into Factors***Description**

Expands decompositions stored in compact form into factors.

**Usage**

```
expand(x, ...)
```

**Arguments**

`x` a matrix decomposition.  
`...` further arguments passed to or from other methods.

**Details**

This is a generic function with special methods for different types of decompositions, see [showMethods](#) (`expand`) to list them all.

**Value**

The expanded decomposition, typically a list of matrix factors.

**Note**

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `expand` allows all factors to be fully expanded.

**See Also**

The LU [lu](#), and the [Cholesky](#) decompositions which have `expand` methods; [facmul](#).

**Examples**

```
(x <- Matrix(round(rnorm(9), 2), 3, 3))
(ex <- expand(lux <- lu(x)))
```

---

expm*Matrix Exponential*

---

### Description

Compute the exponential of a matrix.

### Usage

`expm(x)`

### Arguments

`x` a matrix, typically inheriting from the `dMatrix` class.

### Details

The exponential of a matrix is defined as the infinite Taylor series  $\text{expm}(A) = I + A + A^2/2! + A^3/3! + \dots$  (although this is definitely not the way to compute it). The method for the `dgeMatrix` class uses Ward's diagonal Pade' approximation with three step preconditioning.

### Value

The matrix exponential of `x`.

### Note

The **expm** package contains newer (partly faster and more accurate) algorithms for `expm()` and includes `logm` and `sqrtnm`.

### Author(s)

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

### References

[http://en.wikipedia.org/wiki/Matrix\\_exponential](http://en.wikipedia.org/wiki/Matrix_exponential)

Eric W. Weisstein et al. (1999) *Matrix Exponential*. From MathWorld, <http://mathworld.wolfram.com/MatrixExponential.html>

### See Also

`Schur`; additionally, `expm`, `logm`, etc in package **expm**.

**Examples**

```
(m1 <- Matrix(c(1,0,1,1), nc = 2))
(e1 <- expm(m1)) ; e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), nc = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0, rbind(6*diag(3), 0)))) # sparse!
(e3 <- expm(m3)) # upper triangular
```

externalFormats

*Read and write external matrix formats***Description**

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `sparseMatrix` objects to one of these formats.

**Usage**

```
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

**Arguments**

<code>obj</code>	a real sparse matrix
<code>file</code>	for <code>writeMM</code> - the name of the file to be written. For <code>readHB</code> and <code>readMM</code> the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in <code>".rua"</code> or <code>".rsa"</code> . Those storing matrices in the MatrixMarket format usually end in <code>".mtx"</code> . Alternatively, <code>readHB</code> and <code>readMM</code> accept connection objects.
<code>...</code>	optional additional arguments. Currently none are used in any methods.

**Value**

The `readHB` and `readMM` functions return an object that inherits from the `"Matrix"` class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to `file` in the MatrixMarket format (`writeMM`).

**Note**

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

A very simple way to export small sparse matrices `S`, is to use `summary(S)` which returns a `data.frame` with columns `i`, `j`, and possibly `x`, see `summary` in `sparseMatrix-class`, and an example below.

  readMM(gzcon(url("ftp://math.nist.gov/pub/MatrixMarket2/Harwell-Boeing/counterx/jgl009.mtx"))))

## End(Not run)
data(KNex)
writeMM(KNex$mm, "mmMM.mtx")

## very simple export - in triplet format - to text file:
data(CAex)
s.CA <- summary(CAex)
s.CA # shows (i, j, x) [columns of a data frame]
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
## and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))
## has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))
```

---

facmul

*Multiplication by Decomposition Factors*

---

## Description

Performs multiplication by factors for certain decompositions (and allows explicit formation of those factors).

## Usage

```
facmul(x, factor, y, transpose, left, ...)
```

## Arguments

x	a matrix decomposition. No missing values or IEEE special values are allowed.
factor	an indicator for selecting a particular factor for multiplication.
y	a matrix or vector to be multiplied by the factor or its transpose. No missing values or IEEE special values are allowed.

transpose	a logical value. When FALSE (the default) the factor is applied. When TRUE the transpose of the factor is applied.
left	a logical value. When TRUE (the default) the factor is applied from the left. When FALSE the factor is applied from the right.
...	the method for "qr.Matrix" has additional arguments.

**Value**

the product of the selected factor (or its transpose) and `y`

**NOTE**

Factors for decompositions such as `lu` and `qr` can be stored in a compact form. The function `facmul` allows multiplication without explicit formation of the factors, saving both storage and operations.

**References**

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

**Examples**

```
library(Matrix)
x <- Matrix(rnorm(9), 3, 3)
## Not run:
qrx <- qr(x)                                # QR factorization of x
y <- rnorm(3)
facmul( qr(x), factor = "Q", y)             # form Q y

## End(Not run)
```

---

forceSymmetric

---

*Force a Matrix to 'symmetricMatrix' Without Symmetry Checks*

---

**Description**

Force a square matrix `x` to a [symmetricMatrix](#), **without** a symmetry check as it would be applied for `as(x, "symmetricMatrix")`.

**Usage**

```
forceSymmetric(x, uplo)
```

**Arguments**

<code>x</code>	any square matrix (of numbers), either “traditional” ( <a href="#">matrix</a> ) or inheriting from <a href="#">Matrix</a> .
<code>uplo</code>	optional string, "U" or "L" indicating which “triangle” half of <code>x</code> should determine the result. The default is "U" unless <code>x</code> already has a <code>uplo</code> slot (i.e., when it is <a href="#">symmetricMatrix</a> , or <a href="#">triangularMatrix</a> ), where the default will be <code>x@uplo</code> .

**Value**

a square matrix inheriting from class `symmetricMatrix`.

**See Also**

`symmpart` for the symmetric part of a matrix, or the coercions `as(x, <symmetricMatrix class>)`.

**Examples**

```
## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try( as(hh, "symmetricMatrix") ) # fails, but this works fine:
H6 <- forceSymmetric(hh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)
```

---

formatSparseM

*Formatting Sparse Numeric Matrices Utilities*

---

**Description**

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the `format` and `print` methods for sparse matrices and can be applied as well to standard R matrices. Note that *all* arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of `formatSpMatrix`, the `format` method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

**Usage**

```
formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
              m = as(x, "matrix"), asLogical=NULL, uniDiag=NULL,
              digits=NULL, cx, iN0, dn = dimnames(m))

.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
                   col.names, note.dropping.colnames = TRUE,
                   dn=dimnames(m))
```

**Arguments**

<code>x</code>	an R object inheriting from class <code>sparseMatrix</code> .
<code>zero.print</code>	character which should be used for <i>structural</i> zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like <code>print()</code> ing of non-sparse matrices.
<code>align</code>	a string specifying how the <code>zero.print</code> codes should be aligned, see <code>formatSpMatrix</code> .
<code>m</code>	(optional) a (standard R) <code>matrix</code> version of <code>x</code> .
<code>asLogical</code>	should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for <code>formatSparseM()</code> .
<code>uniDiag</code>	logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are "structural").
<code>digits</code>	significant digits to use for printing, see <code>print.default</code> .
<code>cx</code>	(optional) character matrix; a formatted version of <code>x</code> , still with strings such as "0.00" for the zeros.
<code>iNO</code>	(optional) integer vector, specifying the location of the <i>non</i> -zeroes of <code>x</code> .
<code>col.names, note.dropping.colnames</code>	see <code>formatSpMatrix</code> .
<code>dn</code>	<code>dimnames</code> to be used; a list (of length two) with row and column names (or <code>NULL</code> ).

**Value**

a character matrix like `cx`, where the zeros have been replaced with (padded versions of) `zero.print`. As this is a *dense* matrix, do not use these functions for really large (really) sparse matrices!

**Author(s)**

Martin Maechler

**See Also**

`formatSpMatrix` which calls `formatSparseM()` and is the `format` method for sparse matrices.

`printSpMatrix` which is used by the (typically implicitly called) `show` and `print` methods for sparse matrices.

**Examples**

```
m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11, 0, 0, 0, 0, -7, 0), 4, 9))
fm <- formatSparseM(m)
noquote(fm)
## nice, but this is nicer {with "units" vertically aligned}:
print(fm, quote=FALSE, right=TRUE)
## and "the same" as :
Matrix(m)

## align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m, align="r"))
```

```
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
          (f2 == ".") == (m == 0))
```

---

```
generalMatrix-class
```

*Class "generalMatrix" of General Matrices*

---

## Description

Virtual class of “general” matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

factors ,

Dim ,

Dimnames: all slots inherited from [compMatrix](#); see its description.

## Extends

Class "compMatrix", directly. Class "Matrix", by class "compMatrix".

## See Also

Classes [compMatrix](#), and the non-general virtual classes: [symmetricMatrix](#), [triangularMatrix](#), [diagonalMatrix](#).

---

```
graph-sparseMatrix Conversions "graph" <-> (sparse) Matrix
```

---

## Description

The **Matrix** package has supported conversion from and to "[graph](#)" objects from (Bioconductor) package **graph** since summer 2005, via the usual `as(., "<class>")` coercion,

```
as(from, Class)
```

Since 2013, this functionality is further exposed as the `graph2T()` and `T2graph()` functions (with further arguments than just `from`), which convert graphs to and from the triplet form of sparse matrices (of class "[TsparseMatrix](#)").

## Usage

```
graph2T(from, use.weights = )
T2graph(from, need.uniq = is_not_uniqT(from), edgemode = NULL)
```

**Arguments**

<code>from</code>	for <code>graph2T()</code> , an R object of class "graph"; for <code>T2graph()</code> , a sparse matrix inheriting from " <a href="#">TsparseMatrix</a> ".
<code>use.weights</code>	logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class <a href="#">dgTMatrix</a> ; otherwise the result will be <a href="#">ngTMatrix</a> or <a href="#">nsTMatrix</a> , the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used.
<code>need.uniq</code>	a logical indicating if <code>from</code> may need to be internally “uniquified”; do not set this and hence rather use the default, unless you know what you are doing!
<code>edgemode</code>	one of <code>NULL</code> , "directed", or "undirected". The default <code>NULL</code> looks if the matrix is symmetric and assumes "undirected" in that case.

**Value**

For `graph2T()`, a sparse matrix inheriting from "[TsparseMatrix](#)".

For `T2graph()` an R object of class "graph".

**See Also**

Note that the CRAN package **igraph** also provides conversions from and to sparse matrices (of package **Matrix**) via its [graph.adjacency\(\)](#) and [get.adjacency\(\)](#).

**Examples**

```
if(isTRUE(try(require(graph)))) { ## super careful .. for "checking reasons"
  n4 <- LETTERS[1:4]; dns <- list(n4,n4)
  show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
  show(g1 <- as(a1, "graph")) # directed
  unlist(edgeWeights(g1)) # all '2'

  show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
  show(g2 <- as(a2, "graph")) # directed
  # now if you want it undirected:
  show(g3 <- T2graph(as(a2,"TsparseMatrix"), edgemode="undirected"))
  show(m3 <- as(g3,"Matrix"))
  show( graph2T(g3) ) # a "pattern Matrix" (nsTMatrix)

  a. <- sparseMatrix(i= 4:1, j=1:4, dimnames=list(n4,n4), giveC=FALSE) # no 'x'
  show(a.) # "ngTMatrix"
  show(g. <- as(a., "graph"))

}
```

**Description**

Generate the  $n$  by  $n$  symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large  $n$ , they are often used for testing numerical linear algebra code.

**Usage**

```
Hilbert(n)
```

**Arguments**

`n` a non-negative integer.

**Value**

the  $n$  by  $n$  symmetric Hilbert matrix as a "dpoMatrix" object.

**See Also**

the class `dpoMatrix`

**Examples**

```
Hilbert(6)
```

---

image-methods

*Methods for image() in Package 'Matrix'*

---

**Description**

Methods for function `image` in package **Matrix**. An image of a matrix simply color codes all matrix entries and draws the  $n \times m$  matrix using an  $n \times m$  grid of (colored) rectangles.

The **Matrix** package image methods are based on `levelplot()` from package **lattice**; hence these methods return an “object” of class "trellis", producing a graphic when (auto-) `print()`ed.

**Usage**

```
## S4 method for signature 'dgTMatrix'
image(x,
      xlim = c(1, di[2]),
      ylim = c(di[1], 1), aspect = "iso",
      sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
      xlab = "Column", ylab = "Row", cuts = 15,
      useRaster = FALSE,
      useAbs = NULL, colorkey = !useAbs,
      col.regions = NULL,
      lwd = NULL, ...)
```

**Arguments**

<code>x</code>	a Matrix object, i.e., fulfilling <code>is(x, "Matrix")</code> .
<code>xlim</code> , <code>ylim</code>	x- and y-axis limits; may be used to “zoom into” matrix. Note that $x, y$ “feel reversed”: <code>ylim</code> is for the rows (= 1st index) and <code>xlim</code> for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, <code>ylim</code> is always used decreasingly.
<code>aspect</code>	aspect ratio specified as number ( $y/x$ ) or string; see <code>levelplot</code> .

<code>sub, xlab, ylab</code>	axis annotation with sensible defaults; see <code>plot.default</code> .
<code>cuts</code>	number of levels the range of matrix values would be divided into.
<code>useRaster</code>	logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, <code>panel.levelplot.raster</code> (from <b>lattice</b> package) is used, and the colorkey is also done via rasters, see also <code>levelplot</code> and possibly <code>grid.raster</code> . Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions).
<code>useAbs</code>	logical indicating if <code>abs(x)</code> should be shown; if TRUE, the former (implicit) default, the default <code>col.regions</code> will be <code>grey</code> colors (and no <code>colorkey</code> drawn). The default is FALSE unless the matrix has no negative entries.
<code>colorkey</code>	logical indicating if a color key aka 'legend' should be produced. Default is to draw one, unless <code>useAbs</code> is true. You can also specify a <code>list</code> , see <code>levelplot</code> , such as <code>list(raster=TRUE)</code> in the case of rastering.
<code>col.regions</code>	vector of gradually varying colors; see <code>levelplot</code> .
<code>lwd</code>	(only used when <code>useRaster</code> is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by <code>grid.rect</code> ). The default depends on the matrix dimension and the device size.
<code>...</code>	further arguments passed to methods and <code>levelplot</code> , notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseeding <code>cuts</code> above).

## Value

as all **lattice** graphics functions, `image(<Matrix>)` returns a "trellis" object, effectively the result of `levelplot()`.

## Methods

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

## See Also

`levelplot`, and `print.trellis` from package **lattice**.

## Examples

```
showMethods(image)
## If you want to see all the methods' implementations:
showMethods(image, incl=TRUE, inherit=FALSE)

data(CAex)
image(CAex, main = "image(CAex)")
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)")

cCA <- Cholesky(crossprod(CAex), Imult = .01)
## See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)"),
      split=c(x=1,y=1,nx=2, ny=1), more=TRUE)
```

```

print(image(cCA, useAbs=TRUE),
      split=c(x=2,y=1,nx=2,ny=1))

data(USCounties)
image(USCounties)# huge
image(sign(USCounties))## just the pattern
# how the result looks, may depend heavily on
# the device, screen resolution, antialiasing etc
# e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
# again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
## Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=.5 )
image(USCounties, c(1,300), c(1,200), lwd=.01)

if(doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA")) ||
  identical("true", unname(Sys.getenv("R_PKG_CHECKING_doExtras")))) {
  ## Using raster graphics: For PDF this would give a 77 MB file,
  ## however, for such a large matrix, this is typically considerably
  ## *slower* (than vector graphics rectangles) in most cases :
  if(doPNG <- !dev.interactive())
    png("image-USCounties-raster.png", width=3200, height=3200)
  image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
  if(doPNG)
    dev.off()
  ## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)

```

---

index-class

---

*Virtual Class "index" - Simple Class for Matrix Indices*

---

## Description

The class "index" is a virtual class used for indices (in signatures) for matrix indexing and sub-assignment of **"Matrix"** matrices.

In fact, it is currently implemented as a simple class union ([setClassUnion](#)) of "numeric", "logical" and "character".

## Objects from the Class

Since it is a virtual Class, no objects may be created from it.

## See Also

[\[-methods\]](#), and  
[Subassign-methods](#), also for examples.

## Examples

```
showClass("index")
```

## Description

The "indMatrix" class is the class of index matrices, stored as 1-based integer index vectors. An index matrix is a matrix with exactly one non-zero entry per row. Index matrices are useful for mapping observations to unique covariate values, for example.

Matrix (vector) multiplication with index matrices is equivalent to replicating and permuting rows, or “sampling rows with replacement”, and is implemented that way in the **Matrix** package, see the ‘Details’ below.

## Details

Matrix (vector) multiplication with index matrices from the left is equivalent to replicating and permuting rows of the matrix on the right hand side. (Similarly, matrix multiplication with the transpose of an index matrix from the right corresponds to selecting *columns*.) The crossproduct of an index matrix  $M$  with itself is a diagonal matrix with the number of entries in each column of  $M$  on the diagonal, i.e.,  $M'M = \text{Diagonal}(x = \text{table}(M@perm))$ .

Permutation matrices (of class `pMatrix`) are special cases of index matrices: They are square, of dimension, say,  $n \times n$ , and their index vectors contain exactly all of  $1:n$ .

While “row-indexing” (of more than one row *or* using `drop=FALSE`) stays within the "indMatrix" class, all other subsetting/indexing operations (“column-indexing”, including, `diag`) on "indMatrix" objects treats them as nonzero-pattern matrices ("ngTMatrix" specifically), such that non-matrix subsetting results in `logical` vectors. Sub-assignment (`M[i, j] <- v`) is not sensible and hence an error for these matrices.

## Objects from the Class

Objects can be created by calls of the form `new("indMatrix", ...)` or by coercion from an integer index vector, see below.

## Slots

**perm:** An integer, 1-based index vector, i.e. an integer vector of length `Dim[1]` whose elements are taken from `1:Dim[2]`.

**Dim:** `integer` vector of length two. In some applications, the matrix will be skinny, i.e., with at least as many rows as columns.

**Dimnames:** a `list` of length two where each component is either `NULL` or a `character` vector of length equal to the corresponding `Dim` element.

## Extends

Class "`sparseMatrix`" and "`generalMatrix`", directly.

## Methods

**%%** signature(x = "matrix", y = "indMatrix") and other signatures (use `showMethods("%*%", class="indMatrix")`): ...

**coerce** signature(from = "integer", to = "indMatrix"): This enables typical "indMatrix" construction, given an index vector from elements in 1:Dim[2], see the first example.

**coerce** signature(from = "numeric", to = "indMatrix"): a user convenience, to allow `as(perm, "indMatrix")` for numeric perm with integer values.

**coerce** signature(from = "list", to = "indMatrix"): The list must have two (integer-valued) entries: the first giving the index vector with elements in 1:Dim[2], the second giving Dim[2]. This allows "indMatrix" construction for cases in which the values represented by the rightmost column(s) are not associated with any observations, i.e., in which the index does not contain values Dim[2], Dim[2]-1, Dim[2]-2, ...

**coerce** signature(from = "indMatrix", to = "matrix"): coercion to a traditional FALSE/TRUE **matrix** of **mode** logical.

**coerce** signature(from = "indMatrix", to = "ngTMatrix"): coercion to sparse logical matrix of class **ngTMatrix**.

**t** signature(x = "indMatrix"): return the transpose of the index matrix (which is no longer an indMatrix, but of class **ngTMatrix**).

**colSums, colMeans, rowSums, rowMeans** signature(x = "indMatrix"): return the column or row sums or means.

**rbind2** signature(x = "indMatrix", y = "indMatrix"): a fast method for row-wise catenation of two index matrices (with the same number of columns).

**kronecker** signature(X = "indMatrix", Y = "indMatrix"): return the kronecker product of two index matrices, which corresponds to the index matrix of the interaction of the two.

## Author(s)

Fabian Scheipl, Uni Muenchen, building on existing "pMatrix", after a nice hike's conversation with Martin Maechler and tweaks by the latter.

## See Also

The permutation matrices **pMatrix** are special index matrices. The "pattern" matrices, **nMatrix** and its subclasses.

## Examples

```
p1 <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == p1[rep(1:3, each=3),]))

## row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(p1[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
## random index matrix for 30 observations and 10 unique values:
(s10 <- as(sample(10, 30, replace=TRUE), "indMatrix"))

## Sample rows of a numeric matrix :
```

```

(mm <- matrix(1:10, nrow=10, ncol=3))
s10 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1, IM2))
## same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

# 3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")
# 3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")

as(sml, "ngTMatrix")
s10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)
s10[1:4, ] # preserves "indMatrix"-class

I1 <- as(c(5:1, 6:4, 7:3), "indMatrix")
I2 <- as(7:1, "pMatrix")
(I12 <- suppressWarnings(rBind(I1, I2)))
stopifnot(is(I12, "indMatrix"),
           if(getRversion() >= "3.2.0") identical(I12, rbind(I1, I2)) else TRUE,
           colSums(I12) == c(2L, 2:4, 4:2))

```

invPerm

*Inverse Permutation Vector*

## Description

From a permutation vector *p*, compute its *inverse* permutation vector.

## Usage

```
invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

## Arguments

<i>p</i>	an integer vector of length, say, <i>n</i> .
<i>zero.p</i>	logical indicating if <i>p</i> contains values 0:( <i>n</i> -1) or rather (by default, <i>zero.p</i> = FALSE) 1: <i>n</i> .
<i>zero.res</i>	logical indicating if the result should contain values 0:( <i>n</i> -1) or rather (by default, <i>zero.res</i> = FALSE) 1: <i>n</i> .

## Value

an integer vector of the same length (*n*) as *p*. By default, (*zero.p* = FALSE, *zero.res* = FALSE), `invPerm(p)` is the same as `order(p)` or `sort.list(p)` and for that case, the function is equivalent to `invPerm. <- function(p) { p[p] <- seq_along(p) ; p }`.

**Author(s)**

Martin Maechler

**See Also**the class of permutation matrices, [pMatrix](#).**Examples**

```
p <- sample(10) # a random permutation vector
ip <- invPerm(p)
p[ip] # == 1:10
## they are indeed inverse of each other:
stopifnot(
  identical(p[ip], 1:10),
  identical(ip[p], 1:10),
  identical(invPerm(ip), p)
)
```

is.na-methods

*is.na(), is.infinite() Methods for 'Matrix' Objects***Description**

Methods for function [is.na\(\)](#), [is.finite\(\)](#), and [is.infinite\(\)](#) for all Matrices (objects extending the [Matrix](#) class):

**x = "denseMatrix"** returns a "nMatrix" object of same dimension as x, with TRUE's whenever x is [NA](#), finite, or infinite, respectively.

**x = "sparseMatrix"** ditto.

**Usage**

```
## S4 method for signature 'sparseMatrix'
is.na(x)
## S4 method for signature 'dsparseMatrix'
is.finite(x)
## S4 method for signature 'ddenseMatrix'
is.infinite(x)
## ...
## and for other classes

## S4 method for signature 'xMatrix'
anyNA(x)
## S4 method for signature 'nsparseMatrix'
anyNA(x)
## S4 method for signature 'sparseVector'
anyNA(x)
## S4 method for signature 'nsparseVector'
anyNA(x)
```

**Arguments**

`x` sparse or dense matrix or sparse vector (here; any R object in general).

**See Also**

`NA`, `is.na`, `is.finite`, `is.infinite`, `nMatrix`, `denseMatrix`, `sparseMatrix`.

The `sparseVector` class.

**Examples**

```
M <- Matrix(1:6, nrow=4, ncol=3,
            dimnames = list(c("a", "b", "c", "d"), c("A", "B", "C")))
stopifnot(all(!is.na(M)))
M[2:3,2] <- NA
is.na(M)
if(exists("anyNA", mode="function"))
  anyNA(M)

A <- spMatrix(10,20, i = c(1,3:8),
              j = c(2,9,6:10),
              x = 7 * (1:7))
stopifnot(all(!is.na(A)))

A[2,3] <- A[1,2] <- A[5, 5:9] <- NA
inA <- is.na(A)
stopifnot(sum(inA) == 1+1+5)
```

---

is.null.DN

---

Are the Dimnames dn NULL-like ?

---

**Description**

Are the `dimnames` dn NULL-like?

`is.null.DN(dn)` is less strict than `is.null(dn)`, because it is also true (`TRUE`) when the `dimnames` dn are “like” `NULL`, or `list(NULL, NULL)`, as they can easily be for the traditional R matrices (`matrix`) which have no formal `class` definition, and hence much freedom in how their `dimnames` look like.

**Usage**

```
is.null.DN(dn)
```

**Arguments**

`dn` `dimnames()` of a `matrix`-like R object.

**Value**

logical `TRUE` or `FALSE`.

**Note**

This function is really to be used on “traditional” matrices rather than those inheriting from [Matrix](#), as the latter will always have `dimnames` `list(NULL, NULL)` exactly, in such a case.

**Author(s)**

Martin Maechler

**See Also**

[is.null](#), [dimnames](#), [matrix](#).

**Examples**

```
m <- matrix(round(100 * rnorm(6)), 2, 3); m1 <- m2 <- m3 <- m4 <- m
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()), 2)

m4 ## prints absolutely identically to m

stopifnot(m == m1, m1 == m2, m2 == m3, m3 == m4,
  identical(capture.output(m) -> cm,
    capture.output(m1)),
  identical(cm, capture.output(m2)),
  identical(cm, capture.output(m3)),
  identical(cm, capture.output(m4)))
```

---

isSymmetric-methods

*Methods for Function isSymmetric in Package 'Matrix'*

---

**Description**

`isSymmetric(M)` returns a [logical](#) indicating if `M` is a symmetric matrix. This (now) is a **base** function with a default method for the traditional matrices of [class](#) `"matrix"`. Methods here are defined for virtual Matrix classes such that it works for all objects inheriting from class [Matrix](#).

**See Also**

[forceSymmetric](#), [symmpart](#), and the formal class (and subclasses) `"symmetricMatrix"`.

**Examples**

```
isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2, 2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "dgeMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE

## Look at implementations:
showMethods("isSymmetric", includeDefs=TRUE) # "ANY": base's S3 generic; 6 more
```

isTriangular

*isTriangular() and isDiagonal() Methods***Description**

`isTriangular(M)` returns a `logical` indicating if `M` is a triangular matrix. Analogously, `isDiagonal(M)` is true iff `M` is a diagonal matrix.

Contrary to `isSymmetric()`, these two functions are generically from package **Matrix**, and hence also define methods for traditional (`class` "matrix") matrices.

By our definition, triangular, diagonal and symmetric matrices are all *square*, i.e. have the same number of rows and columns.

**Usage**

```
isDiagonal(object)
```

```
isTriangular(object, upper = NA, ...)
```

**Arguments**

<code>object</code>	any R object, typically a matrix (traditional or Matrix package).
<code>upper</code>	logical, one of NA (default), FALSE, or TRUE where the last two cases require a lower or upper triangular object to result in TRUE.
<code>...</code>	potentially further arguments for other methods.

**Value**

a ("scalar") logical, TRUE or FALSE, never NA. For `isTriangular()`, if the result is TRUE, it may contain an attribute (see `attributes` "kind", either "L" or "U" indicating if it is a lower or upper triangular matrix).

**See Also**

`isSymmetric`; formal class (and subclasses) `"triangularMatrix"` and `"diagonalMatrix"`.

**Examples**

```
isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "dgeMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE
```

KhatriRao

*Khatri-Rao Matrix Product***Description**

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

**Usage**

```
KhatriRao(X, Y = X, FUN = "*", make.dimnames = FALSE)
```

**Arguments**

`X, Y` matrices of with the same number of columns.

`FUN` the (name of the) [function](#) to be used for the column-wise Kronecker products, see [kronecker](#), defaulting to the usual multiplication.

`make.dimnames` logical indicating if the result should inherit [dimnames](#) from `X` and `Y` in a simple way.

**Value**

a "[CsparseMatrix](#)", say `R`, the Khatri-Rao product of `X` ( $n \times k$ ) and `Y` ( $m \times k$ ), is of dimension  $(n \cdot m) \times k$ , where the  $j$ -th column, `R[, j]` is the kronecker product [kronecker](#)(`X[, j]`, `Y[, j]`).

**Note**

The current implementation is efficient for large sparse matrices.

**Author(s)**

Michael Cysouw, Univ. Marburg; minor tweaks by Martin Maechler.

## Examples

```
## Example with very small matrices:
m <- matrix(1:12,3,4)
d <- diag(1:4)
KhatriRao(m,d)
KhatriRao(d,m)
dimnames(m) <- list(LETTERS[1:3], letters[1:4])
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(NULL, paste0("D", 1:4))
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)
dimnames(d) <- list(paste0("d", 10*1:4), paste0("D", 1:4))
KhatriRao(m,d, make.dimnames=TRUE)
KhatriRao(d,m, make.dimnames=TRUE)

nm <- as(m, "nMatrix")
nd <- as(d, "nMatrix")
KhatriRao(nm,nd, make.dimnames=TRUE)
KhatriRao(nd,nm, make.dimnames=TRUE)

stopifnot(dim(KhatriRao(m,d)) == c(nrow(m)*nrow(d), ncol(d)))
```

---

KNex

---

*Koenker-Ng Example Sparse Model Matrix and Response Vector*

---

## Description

A model matrix `mm` and corresponding response vector `y` used in an example by Koenker and Ng. The matrix `mm` is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector `y` is just `numeric` of length 1850.

## Usage

```
data(KNex)
```

## References

Roger Koenker and Pin Ng (2003). SparseM: A sparse matrix package for R; *J. of Statistical Software*, **8** (6), <http://www.jstatsoft.org/>

## Examples

```
data(KNex)
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time( # a fraction of a second
  sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))

head(round(sparse.sol,3))
```

```
## Compare with QR-based solution ("more accurate, but slightly slower"):
system.time(
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y) ))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE
```

---

kronecker-methods    *Methods for Function 'kronecker()' in Package 'Matrix'*

---

## Description

Computes Kronecker products for objects inheriting from "Matrix".

In order to preserve sparseness, we treat  $0 * NA$  as 0, not as NA as usually in R (and as used for the base function `kronecker`).

## Methods

```
kronecker signature(X = "Matrix", Y = "ANY") .....
kronecker signature(X = "ANY", Y = "Matrix") .....
kronecker signature(X = "diagonalMatrix", Y = "ANY") .....
kronecker signature(X = "sparseMatrix", Y = "ANY") .....
kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix") .....
kronecker signature(X = "dgTMatrix", Y = "dgTMatrix") .....
kronecker signature(X = "dtTMatrix", Y = "dtTMatrix") .....
kronecker signature(X = "indMatrix", Y = "indMatrix") .....
```

## Examples

```
(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
(t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12

## should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "nsparseMatrix"))
N2 <- as(N, "generalMatrix")
MM <- kronecker(M,M)
NN <- kronecker(N,N)
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
           is(NN, "triangularMatrix"))
```

---

ldenseMatrix-class *Virtual Class "ldenseMatrix" of Dense Logical Matrices*

---

### Description

ldenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both [denseMatrix](#) and [lMatrix](#) directly.

### Slots

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see [Matrix](#).

### Extends

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

### Methods

**coerce** signature(from = "matrix", to = "ldenseMatrix"):...

**coerce** signature(from = "ldenseMatrix", to = "matrix"):...

**as.vector** signature(x = "ldenseMatrix", mode = "missing"):...

**which** signature(x = "ndenseMatrix"), semantically equivalent to **base** function [which](#)(x, arr.ind); for details, see the [lMatrix](#) class documentation.

### See Also

Class [lgeMatrix](#) and the other subclasses.

### Examples

```
showClass("ldenseMatrix")
```

```
as(diag(3) > 0, "ldenseMatrix")
```

---

ldiMatrix-class *Class "ldiMatrix" of Diagonal Logical Matrices*

---

### Description

The class "ldiMatrix" of logical diagonal matrices.

### Objects from the Class

Objects can be created by calls of the form `new("ldiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x:** "logical" vector.

**diag:** "character" string, either "U" or "N", see [ddiMatrix](#).

**Dim,Dimnames:** matrix dimension and [dimnames](#), see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)" and class "[lMatrix](#)", directly.

Class "[sparseMatrix](#)", by class "[diagonalMatrix](#)".

**See Also**

Classes [ddiMatrix](#) and [diagonalMatrix](#); function [Diagonal](#).

**Examples**

```
(lM <- Diagonal(x = c(TRUE,FALSE,FALSE)))
str(lM) #> gory details (slots)

crossprod(lM) # numeric
(nM <- as(lM, "nMatrix")) # -> sparse (not formally ``diagonal'')
crossprod(nM) # logical sparse
```

---

lgeMatrix-class	<i>Class "lgeMatrix" of General Dense Logical Matrices</i>
-----------------	--

---

**Description**

This is the class of general dense [logical](#) matrices.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Class "[ldenseMatrix](#)", directly. Class "[lMatrix](#)", by class "[ldenseMatrix](#)". Class "[denseMatrix](#)", by class "[ldenseMatrix](#)". Class "[Matrix](#)", by class "[ldenseMatrix](#)". Class "[Matrix](#)", by class "[ldenseMatrix](#)".

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#)); use, e.g., [showMethods](#)(class="lgeMatrix") for details.

**See Also**

Non-general logical dense matrix classes such as `ltrMatrix`, or `lsyMatrix`; *sparse* logical classes such as `lgCMatrix`.

**Examples**

```
showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4, 7) > 0)) # a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4, 7) > 0)) # a simple random lgCMatrix
as(lM, "lgCMatrix")
```

---

lsparseMatrix-classes

*Sparse logical matrices*

---

**Description**

The `lsparseMatrix` class is a virtual class of sparse matrices with TRUE/FALSE or NA entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (class `TsparseMatrix`, subclasses `lgTMatrix`, `lsTMatrix`, and `ltTMatrix`) or in compressed column-oriented form (class `CsparseMatrix`, subclasses `lgCMatrix`, `lsCMatrix`, and `ltCMatrix`) or—rarely—in compressed row-oriented form (class `RsparseMatrix`, subclasses `lgRMatrix`, `lsRMatrix`, and `ltRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

**Details**

Note that triplet stored (`TsparseMatrix`) matrices such as `lgTMatrix` may contain duplicated pairs of indices  $(i, j)$  as for the corresponding numeric class `dgTMatrix` where for such pairs, the corresponding `x` slot entries are added. For logical matrices, the `x` entries corresponding to duplicated index pairs  $(i, j)$  are “added” as well if the addition is defined as logical *or*, i.e., “TRUE + TRUE  $\rightarrow$  TRUE” and “TRUE + FALSE  $\rightarrow$  TRUE”. Note the use of `uniqTsparse()` for getting an internally unique representation without duplicated  $(i, j)$  entries.

**Objects from the Class**

Objects can be created by calls of the form `new("lgCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression `x != 0`.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

## Slots

- x:** Object of class "logical", i.e., either TRUE, [NA](#), or FALSE.
- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.
- Dim:** Object of class "integer" - the dimensions of the matrix.

## Methods

- coerce** signature(from = "dgCMatrix", to = "lgCMatrix")
- t** signature(x = "lgCMatrix"): returns the transpose of x
- which** signature(x = "lsparseMatrix"), semantically equivalent to **base** function [which](#)(x, arr.ind); for details, see the [lMatrix](#) class documentation.

## See Also

the class [dgCMatrix](#) and [dgTMatrix](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm           # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
           identical(!lm, m <= 1))

data(KNex)
str(mmG.1 <- (KNex $ mm) > 0.1) # "lgC..."
table(mmG.1@x) # however with many ``non-structural zeros''
## from logical to nz_pattern -- okay when there are no NA's :
nmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
## from logical to "double"
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix") # has no extra FALSE, i.e. drop0() included
stopifnot(identical(nmG.1, as((KNex $ mm) != 0, "nMatrix")),
           validObject(lmG.1), all(lmG.1@x),
           # same "logical" but lmG.1 has no 'FALSE' in x slot:
           all(lmG.1 == mmG.1))

class(xnx <- crossprod(nmG.1)) # "nsC.."
class(xlx <- crossprod(mmG.1)) # "dsC.." : numeric
```

```
is0 <- (x1x == 0)
mean(as.vector(is0))# 99.3% zeros: quite sparse, but
table(x1x@x == 0)# more than half of the entries are (non-structural!) 0
stopifnot(isSymmetric(x1x), isSymmetric(xnx),
  ## compare xnx and x1x : have the *same* non-structural 0s :
  sapply(slotNames(xnx),
    function(n) identical(slot(xnx, n), slot(x1x, n))))
```

lsyMatrix-class

*Symmetric Dense Logical Matrices*

## Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "lspMatrix" is the class of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("lsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Both extend classes "[ldenseMatrix](#)" and "[symmetricMatrix](#)", directly; further, class "[Matrix](#)" and others, *indirectly*. Use `showClass("lsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="dsyMatrix")` for details.

## See Also

[lgeMatrix](#), [Matrix](#), [t](#)

## Examples

```
(M2 <- Matrix(c(TRUE, NA,FALSE,FALSE), 2,2)) # logical dense (ltr)
str(M2)
# can
(sM <- M2 | t(M2)) # "lge"
as(sM, "lsyMatrix")
str(sM <- as(sM, "lspMatrix")) # packed symmetric
```

---

ltrMatrix-class      *Triangular Dense Logical Matrices*

---

**Description**

The "ltrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ltpMatrix" class is the same except in packed storage.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Both extend classes "[ldenseMatrix](#)" and "[triangularMatrix](#)", directly; further, class "[Matrix](#)", "[lMatrix](#)" and others, indirectly. Use [showClass](#)("ltrMatrix"), e.g., for details.

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods](#)(class="ltpMatrix") for details.

**See Also**

Classes [lgeMatrix](#), [Matrix](#); function [t](#)

**Examples**

```
showClass("ltrMatrix")

str(new("ltpMatrix"))
(lutr <- as(upper.tri(matrix(,4,4)), "ltrMatrix"))
str(lutp <- as(lutr, "ltpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!lutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(lutp, as(!lutp, "ltpMatrix")))
```

---

lu *(Generalized) Triangular Decomposition of a Matrix*

---

**Description**

Computes (generalized) triangular decompositions of square (sparse or dense) and non-square dense matrices.

**Usage**

```
lu(x, ...)
## S4 method for signature 'matrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = TRUE, tol = 1,
    keep.dimnames = TRUE, ...)
```

**Arguments**

x	a dense or sparse matrix, in the latter case of square dimension. No missing values or IEEE special values are allowed.
warnSing	(when x is a " <a href="#">denseMatrix</a> ") logical specifying if a <a href="#">warning</a> should be signalled when x is singular.
errSing	(when x is a " <a href="#">sparseMatrix</a> ") logical specifying if an error (see <a href="#">stop</a> ) should be signalled when x is singular. When x is singular, <code>lu(x, errSing=FALSE)</code> returns <a href="#">NA</a> instead of an LU decomposition. No warning is signalled and the user should be careful in that case.
order	logical or integer, used to choose which fill-reducing permutation technique will be used internally. Do not change unless you know what you are doing.
tol	positive number indicating the pivoting tolerance used in <code>cs_lu</code> . Do only change with much care.
keep.dimnames	logical indicating that <a href="#">dimnames</a> should be propagated to the result, i.e., "kept". This was hardcoded to <code>FALSE</code> in upto <b>Matrix</b> version 1.2-0. Setting to <code>FALSE</code> may gain some performance.
...	further arguments passed to or from other methods.

**Details**

`lu()` is a generic function with special methods for different types of matrices. Use `showMethods("lu")` to list all the methods for the `lu` generic.

The method for class `dgeMatrix` (and all dense matrices) is based on LAPACK's "dgetrf" subroutine. It returns a decomposition also for singular and non-square matrices.

The method for class `dgCMatrix` (and all sparse matrices) is based on functions from the CSparse library. It signals an error (or returns `NA`, when `errSing = FALSE`, see above) when the decomposition algorithm fails, as when x is (too close to) singular.

**Value**

An object of class "LU", i.e., "[denseLU](#)" (see its separate help page), or "[sparseLU](#)", see [sparseLU](#); this is a representation of a triangular decomposition of  $x$ .

**Note**

Because the underlying algorithm differ entirely, in the *dense* case (class [denseLU](#)), the decomposition is

$$A = PLU,$$

where as in the *sparse* case (class [sparseLU](#)), it is

$$A = P'LUQ.$$

**Examples**

```
##--- Dense -----
x <- Matrix(rnorm(9), 3, 3)
lu(x)
dim(x2 <- round(10 * x[, -3])) # non-square
expand(lu2 <- lu(x2))

##--- Sparse (see more in ?"sparseLU-class")----- % ./sparseLU-class.Rd

pm <- as(readMM(system.file("external/pores_1.mtx",
                           package = "Matrix")),
         "CsparseMatrix")
str(pmLU <- lu(pm)) # p is a 0-based permutation of the rows
                   # q is a 0-based permutation of the columns
## permute rows and columns of original matrix
ppm <- pm[pmLU@p + 1L, pmLU@q + 1L]
pLU <- drop0(pmLU@L %*% pmLU@U) # L %*% U -- dropping extra zeros
## equal up to "rounding"
ppm[1:14, 1:5]
pLU[1:14, 1:5]
```

---

LU-class

LU (dense) Matrix Decompositions

---

## Description

The "LU" class is the *virtual* class of LU decompositions of real matrices. "denseLU" the class of LU decompositions of dense real matrices.

## Details

The decomposition is of the form

$$A = PLU$$

where typically all matrices are of size  $n \times n$ , and the matrix  $P$  is a permutation matrix,  $L$  is lower triangular and  $U$  is upper triangular (both of class [dtrMatrix](#)).

Note that the *dense* decomposition is also implemented for a  $m \times n$  matrix  $A$ , when  $m \neq n$ .

If  $m < n$  ("wide case"),  $U$  is  $m \times n$ , and hence not triangular.

If  $m > n$  ("long case"),  $L$  is  $m \times n$ , and hence not triangular.

## Objects from the Class

Objects can be created by calls of the form `new("denseLU", ...)`. More commonly the objects are created explicitly from calls of the form `lu(mm)` where `mm` is an object that inherits from the "dgeMatrix" class or as a side-effect of other functions applied to "dgeMatrix" objects.

## Extends

"LU" directly extends the virtual class "[MatrixFactorization](#)".

"denseLU" directly extends "LU".

## Slots

**x:** object of class "numeric". The "L" (unit lower triangular) and "U" (upper triangular) factors of the original matrix. These are stored in a packed format described in the Lapack manual, and can be retrieved by the `expand()` method, see below.

**perm:** Object of class "integer" - a vector of length `min(Dim)` that describes the permutation applied to the rows of the original matrix. The contents of this vector are described in the Lapack manual.

**Dim:** the dimension of the original matrix; inherited from class [MatrixFactorization](#).

## Methods

**expand** signature(`x = "denseLU"`): Produce the "L" and "U" (and "P") factors as a named list of matrices, see also the example below.

**solve** signature(`a = "denseLU"`, `b = "missing"`): Compute the inverse of  $A$ ,  $A^{-1}$ , `solve(A)` using the LU decomposition, see also [solve-methods](#).

**See Also**

class [sparseLU](#) for LU decompositions of *sparse* matrices; further, class [dgeMatrix](#) and functions [lu](#), [expand](#).

**Examples**

```
set.seed(1)
mm <- Matrix(round(rnorm(9),2), nrow = 3)
mm
str(lum <- lu(mm))
elu <- expand(lum)
elu # three components: "L", "U", and "P", the permutation
elu$L %*% elu$U
(m2 <- with(elu, P %*% L %*% U)) # the same as 'mm'
stopifnot(all.equal(as(mm, "matrix"),
                    as(m2, "matrix")))
```

Matrix

*Construct a Classed Matrix***Description**

Construct a Matrix of a class that inherits from `Matrix`.

**Usage**

```
Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
       sparse = NULL, doDiag = TRUE, forceCheck = FALSE)
```

**Arguments**

<code>data</code>	an optional numeric data vector or matrix.
<code>nrow</code>	when <code>data</code> is not a matrix, the desired number of rows
<code>ncol</code>	when <code>data</code> is not a matrix, the desired number of columns
<code>byrow</code>	logical. If <code>FALSE</code> (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
<code>dimnames</code>	a <a href="#">dimnames</a> attribute for the matrix: a list of two character components. They are set if not <code>NULL</code> (as per default).
<code>sparse</code>	logical or <code>NULL</code> , specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0.  Note that when the resulting matrix is diagonal (“mathematically”), <code>sparse=FALSE</code> results in a <a href="#">diagonalMatrix</a> , unless <code>doDiag=FALSE</code> as well, see the first examples.
<code>doDiag</code>	only when <code>sparse = FALSE</code> , logical indicating if a <a href="#">diagonalMatrix</a> object should be considered (default). Otherwise, in such a case, a dense (symmetric) matrix will be returned.
<code>forceCheck</code>	logical indicating if the checks for structure should even happen when <code>data</code> is already a “Matrix” object.

## Details

If either of `nrow` or `ncol` is not given, an attempt is made to infer it from the length of `data` and the other parameter. Further, `Matrix()` makes efforts to keep `logical` matrices logical, i.e., inheriting from class `lMatrix`, and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a *symmetric* matrix also needs symmetric `dimnames`, e.g., by specifying `dimnames = list(NULL, NULL)`, see the examples.

Most of the time, the function works via a traditional (*full*) `matrix`. However, `Matrix(0, nrow, ncol)` directly constructs an “empty” `sparseMatrix`, as does `Matrix(FALSE, *)`.

Although it is sometime possible to mix unclassed matrices (created with `matrix`) with ones of class `"Matrix"`, it is much safer to always use carefully constructed ones of class `"Matrix"`.

## Value

Returns matrix of a class that inherits from `"Matrix"`. Only if `data` is not a `matrix` and does not already inherit from class `Matrix` are the arguments `nrow`, `ncol` and `byrow` made use of.

## See Also

The classes `Matrix`, `symmetricMatrix`, `triangularMatrix`, and `diagonalMatrix`; further, `matrix`.

Special matrices can be constructed, e.g., via `sparseMatrix` (sparse), `bdiag` (block-diagonal), `bandSparse` (banded sparse), or `Diagonal`.

## Examples

```
Matrix(0, 3, 2) # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE) # -> 'dense'
Matrix(0, 2, 2, sparse=FALSE) # diagonal !
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE) # -> dense
Matrix(1:6, 3, 2) # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

## logical ones:
Matrix(diag(4) > 0) # -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) # -> sparse...
Matrix(diag(4) >= 0) # -> "lsyMatrix" (of all 'TRUE')
## triangular
l3 <- upper.tri(matrix(,3,3))
(M <- Matrix(l3)) # -> "ltCMatrix"
Matrix(! l3) # -> "ltrMatrix"
as(l3, "CsparseMatrix")

Matrix(1:9, nrow=3,
      dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3))) # identity, i.e., unit "diagonalMatrix"
str(I3) # note the empty 'x' slot

(A <- cbind(a=c(2,1), b=1:2)) # symmetric *apart* from dimnames
Matrix(A) # hence 'dgeMatrix'
(As <- Matrix(A, dimnames = list(NULL, NULL))) # -> symmetric
stopifnot(is(As, "symmetricMatrix"),
          is(Matrix(0, 3, 3), "sparseMatrix"),
          is(Matrix(FALSE, 1, 1), "sparseMatrix"))
```

Matrix-class

Virtual Class "Matrix" Class of Matrices

## Description

The `Matrix` class is a class contained by all actual classes in the **Matrix** package. It is a “virtual” class.

## Slots

Common to *all* matrix objects in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

## Methods

**determinant** signature(x = "Matrix", logarithm = "missing"): and

**determinant** signature(x = "Matrix", logarithm = "logical"): compute the (log) determinant of x. The method chosen depends on the actual Matrix class of x. Note that `det` also works for all our matrices, calling the appropriate `determinant()` method. The `Matrix::det` is an exact copy of `base::det`, but in the correct namespace, and hence calling the S4-aware version of `determinant()`.

**diff** signature(x = "Matrix"): As `diff()` for traditional matrices, i.e., applying `diff()` to each column.

**dim** signature(x = "Matrix"): extract matrix dimensions `dim`.

**dim<-** signature(x = "Matrix", value = "ANY"): where value is integer of length 2. Allows to *reshape* Matrix objects, but only when `prod(value) == prod(dim(x))`.

**dimnames** signature(x = "Matrix"): extract `dimnames`.

**dimnames<-** signature(x = "Matrix", value = "list"): set the `dimnames` to a list of length 2, see `dimnames<-`.

**length** signature(x = "Matrix"): simply defined as `prod(dim(x))` (and hence of mode "double").

**show** signature(object = "Matrix"): `show` method for printing.

**image** signature(object = "Matrix"): draws an `image` of the matrix entries, using `levelplot()` from package **lattice**.

**head** signature(object = "Matrix"): return only the “head”, i.e., the first few rows.

**tail** signature(object = "Matrix"): return only the “tail”, i.e., the last few rows of the respective matrix.

**as.matrix, as.array** signature(x = "Matrix"): the same as `as(x, "matrix")`; see also the note below.

**as.vector** signature(x = "Matrix", mode = "missing"): `as.vector(m)` should be identical to `as.vector(as(m, "matrix"))`, implemented more efficiently for some subclasses.

`as(x, "vector")`, `as(x, "numeric")` etc, similarly.

`coerce` signature(`from = "ANY"`, `to = "Matrix"`): This relies on a correct `as.matrix()` method for `from`.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., `colSums`, `rowMeans`. Even **base** functions may work automatically (if they first call `as.matrix()` on their principal argument), e.g., `apply`, `eigen`, `svd` or `kappa` all do work via coercion to a “traditional” (dense) `matrix`.

## Note

Loading the `Matrix` namespace “overloads” `as.matrix` and `as.array` in the **base** namespace by the equivalent of `function(x) as(x, "matrix")`. Consequently, `as.matrix(m)` or `as.array(m)` will properly work when `m` inherits from the "Matrix" class — *also* for functions in package **base** and other packages. E.g., `apply` or `outer` can therefore be applied to "Matrix" matrices.

## Author(s)

Douglas Bates <bates@stat.wisc.edu> and Martin Maechler

## See Also

the classes `dgeMatrix`, `dgCMatrix`, and function `Matrix` for construction (and examples).

Methods, e.g., for `kronecker`.

## Examples

```
slotNames("Matrix")

cl <- getClass("Matrix")
names(cl@subclasses) # more than 40 ..

showClass("Matrix")#> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
## can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
           all.equal(det(cm),
                     determinant(as(cm,"matrix"), log=FALSE)$modulus,
                     check.attributes=FALSE))
```

---

matrix-products      *Matrix (Cross) Products (of Transpose)*

---

**Description**

The basic matrix product, `%*%` is implemented for all our `Matrix` and also for `sparseVector` classes, fully analogously to R's base `matrix` and vector objects.

The functions `crossprod` and `tcrossprod` are matrix products or “cross products”, ideally implemented efficiently without computing `t(.)`'s unnecessarily. They also return `symmetricMatrix` classed matrices when easily detectable, e.g., in `crossprod(m)`, the one argument case.

`tcrossprod()` takes the cross-product of the transpose of a matrix. `tcrossprod(x)` is formally equivalent to, but faster than, the call `x %*% t(x)`, and so is `tcrossprod(x, y)` instead of `x %*% t(y)`.

Boolean matrix products are computed via either `%&%` or `boolArith = TRUE`.

**Usage**

```
## S4 method for signature 'CsparseMatrix,diagonalMatrix'
x %*% y

## S4 method for signature 'dgeMatrix,missing'
crossprod(x, y = NULL, boolArith = NA, ...)
## S4 method for signature 'CsparseMatrix,diagonalMatrix'
crossprod(x, y = NULL, boolArith = NA, ...)
## .... and for many more signatures

## S4 method for signature 'CsparseMatrix,ddenseMatrix'
tcrossprod(x, y = NULL, boolArith = NA, ...)
## S4 method for signature 'TsparseMatrix,missing'
tcrossprod(x, y = NULL, boolArith = NA, ...)
## .... and for many more signatures
```

**Arguments**

<code>x</code>	a matrix-like object
<code>y</code>	a matrix-like object, or for <code>[t]crossprod()</code> <code>NULL</code> (by default); the latter case is formally equivalent to <code>y = x</code> .
<code>boolArith</code>	logical, i.e., <code>NA</code> , <code>TRUE</code> , or <code>FALSE</code> . If true the result is (coerced to) a pattern matrix, i.e., <code>"nMatrix"</code> , unless there are <code>NA</code> entries and the result will be a <code>"lMatrix"</code> . If false the result is (coerced to) numeric. When <code>NA</code> , currently the default, the result is a pattern matrix when <code>x</code> and <code>y</code> are <code>"nsparseMatrix"</code> and numeric otherwise.
<code>...</code>	potentially more arguments passed to and from methods.

**Details**

For some classes in the `Matrix` package, such as `dgcMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

`boolArith = TRUE` for regular (“non cross”) matrix products, `%%` cannot be specified. Instead, we provide the `%&%` operator for *boolean* matrix products.

### Value

A `Matrix` object, in the one argument case of an appropriate symmetric matrix class.

### Methods

`%%` signature(`x = "dgeMatrix"`, `y = "dgeMatrix"`): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%*", class = "dgeMatrix")`.

`%%` signature(`x = "dtrMatrix"`, `y = "matrix"`) and other signatures (use `showMethods("%*", class="dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).

**crossprod** signature(`x = "dgeMatrix"`, `y = "dgeMatrix"`): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of `t(x) %*% y`.

**crossprod** signature(`x = "CsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod** signature(`x = "TsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod, tcrossprod** signature(`x = "dtrMatrix"`, `y = "matrix"`) and other signatures, see `"%&%"` above.

### Note

`boolArith = TRUE, FALSE` or `NA` has been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation may be incomplete and partly missing. Please report such omissions if detected!

Currently, `boolArith = TRUE` is implemented via `CsparseMatrix` coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

### See Also

`tcrossprod` in R’s base, `crossprod` and `%*%`.

### Examples

```
## A random sparse "incidence" matrix :
m <- matrix(0, 400, 500)
set.seed(12)
m[runif(314, 0, length(m))] <- 1
mm <- as(m, "dgCMatrix")
object.size(m) / object.size(mm) # smaller by a factor of > 200

## tcrossprod() is very fast:
system.time(tCmm <- tcrossprod(mm)) # 0 (PIII, 933 MHz)
system.time(cm <- crossprod(t(m))) # 0.16
system.time(cm. <- tcrossprod(m)) # 0.02

stopifnot(cm == as(tCmm, "matrix"))
```

```
## show sparse sub matrix
tCmm[1:16, 1:30]
```

MatrixClass

*The Matrix (Super-) Class of a Class*

## Description

Return the (maybe super-)class of class `cl` from package **Matrix**, returning `character(0)` if there is none.

## Usage

```
MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE,
            dropVirtual = TRUE, ...)
```

## Arguments

<code>cl</code>	string, class name
<code>cld</code>	its class definition
<code>...Matrix</code>	logical indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind.
<code>dropVirtual</code>	logical indicating if virtual classes are included or not.
<code>...</code>	further arguments are passed to <code>.selectSuperClasses()</code> .

## Value

a `character` string

## Author(s)

Martin Maechler, 24 Mar 2009

## See Also

`Matrix`, the mother of all **Matrix** classes.

## Examples

```
mkA <- setClass("A", contains="dgCMatrix")
(A <- mkA())
stopifnot(identical(
  MatrixClass("A"),
  "dgCMatrix"))
```

---

MatrixFactorization-class

Class "MatrixFactorization" of Matrix Factorizations

---

## Description

The class "MatrixFactorization" is the virtual (super) class of (potentially) all matrix factorizations of matrices from package **Matrix**.

The class "CholeskyFactorization" is the virtual class of all Cholesky decompositions from **Matrix** (and trivial sub class of "MatrixFactorization").

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**Dim:** Object of class "integer" - the dimensions of the original matrix - must be an integer vector with exactly two non-negative values.

## Methods

**dim** (x) simply returns x@Dim, see above.

**expand** signature(x = "MatrixFactorization"): this has not been implemented yet for all matrix factorizations. It should return a list whose components are matrices which when multiplied return the original [Matrix](#) object.

**show** signature(object = "MatrixFactorization"): simple printing, see [show](#).

**solve** signature(a = "MatrixFactorization", b= .): solve  $Ax = b$  for  $x$ ; see [solve-methods](#).

## See Also

classes inheriting from "MatrixFactorization", such as [LU](#), [Cholesky](#), [CHMfactor](#), and [sparseQR](#).

## Examples

```
showClass("MatrixFactorization")
getClass("CholeskyFactorization")
```

---

ndenseMatrix-class *Virtual Class "ndenseMatrix" of Dense Logical Matrices*

---

## Description

`ndenseMatrix` is the virtual class of all dense logical (S4) matrices. It extends both `denseMatrix` and `lMatrix` directly.

## Slots

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see `Matrix`.

## Extends

Class "nMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "nMatrix". Class "Matrix", by class "denseMatrix".

## Methods

```
%% signature(x = "nsparseMatrix", y = "ndenseMatrix"):...
%% signature(x = "ndenseMatrix", y = "nsparseMatrix"):...
coerce signature(from = "matrix", to = "ndenseMatrix"):...
coerce signature(from = "ndenseMatrix", to = "matrix"):...
crossprod signature(x = "nsparseMatrix", y = "ndenseMatrix"):...
crossprod signature(x = "ndenseMatrix", y = "nsparseMatrix"):...
as.vector signature(x = "ndenseMatrix", mode = "missing"):...
diag signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the
generic diag().
which signature(x = "ndenseMatrix"), semantically equivalent to base function
which(x, arr.ind); for details, see the lMatrix class documentation.
```

## See Also

Class `ngeMatrix` and the other subclasses.

## Examples

```
showClass("ndenseMatrix")

as(diag(3) > 0, "ndenseMatrix")# -> "nge"
```

nearPD

Nearest Positive Definite Matrix

**Description**

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

**Usage**

```
nearPD(x, corr = FALSE, keepDiag = FALSE, do2eigen = TRUE,
       doSym = FALSE, doDykstra = TRUE, only.values = FALSE,
       ensureSymmetry = !isSymmetric(x),
       eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08,
       maxit = 100, conv.norm.type = "I", trace = FALSE)
```

**Arguments**

x	numeric $n \times n$ approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If x is not symmetric (and ensureSymmetry is not false), <code>symmpart(x)</code> is used.
corr	logical indicating if the matrix should be a <i>correlation</i> matrix.
keepDiag	logical, generalizing corr: if TRUE, the resulting matrix should have the same diagonal ( <code>diag(x)</code> ) as the input matrix.
do2eigen	logical indicating if a <code>posdefify()</code> eigen step should be applied to the result of the Higham algorithm.
doSym	logical indicating if <code>X &lt;- (X + t(X))/2</code> should be done, after <code>X &lt;- tcrossprod(Qd, Q)</code> ; some doubt if this is necessary.
doDykstra	logical indicating if Dykstra's correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration $Y_k = P_U(P_S(Y_{k-1}))$ .
only.values	logical; if TRUE, the result is just the vector of eigen values of the approximating matrix.
ensureSymmetry	logical; by default, <code>symmpart(x)</code> is used whenever <code>isSymmetric(x)</code> is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. <i>Beware</i> however that setting it FALSE for an asymmetric input x, is typically nonsense!
eig.tol	defines relative positiveness of eigenvalues compared to largest one, $\lambda_1$ . Eigen values $\lambda_k$ are treated as if zero when $\lambda_k/\lambda_1 \leq \text{eig.tol}$ .
conv.tol	convergence tolerance for Higham algorithm.
posd.tol	tolerance for enforcing positive definiteness (in the final <code>posdefify</code> step when <code>do2eigen</code> is TRUE).
maxit	maximum number of iterations allowed.
conv.norm.type	convergence norm type ( <code>norm(*, type)</code> ) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham's proposal.
trace	logical or integer specifying if convergence monitoring should be traced.

## Details

This implements the algorithm of Higham (2002), and then (if `do2eigen` is true) forces positive definiteness using code from [posdefify](#). The algorithm of Knol DL and ten Berge (1989) (not implemented here) is more general in (1) that it allows constraints to fix some rows (and columns) of the matrix and (2) to force the smallest eigenvalue to have a certain value.

Note that setting `corr = TRUE` just sets `diag(.) <- 1` within the algorithm.

Higham (2002) uses Dykstra's correction, but the version by Jens Oehlschlaegel did not use it (accidentally), and has still lead to good results; this simplification, now only via `doDykstra = FALSE`, was active in `nearPD()` upto Matrix version 0.999375-40.

## Value

If `only.values = TRUE`, a numeric vector of eigen values of the approximating matrix; Otherwise, as by default, an S3 object of `class "nearPD"`, basically a list with components

<code>mat</code>	a matrix of class <code>dpoMatrix</code> , the computed positive-definite matrix.
<code>eigenvalues</code>	numeric vector of eigen values of <code>mat</code> .
<code>corr</code>	logical, just the argument <code>corr</code> .
<code>normF</code>	the Frobenius norm ( <code>norm(x-X, "F")</code> ) of the difference between the original and the resulting matrix.
<code>iterations</code>	number of iterations needed.
<code>converged</code>	logical indicating if iterations converged.

## Author(s)

Jens Oehlschlaegel donated a first version. Subsequent changes by the Matrix package authors.

A first version of this (with non-optional `corr=TRUE`) has been available as [nearcor\(\)](#); and more simple versions with a similar purpose [posdefify\(\)](#), both from package `sfsmisc`.

## Examples

```
## Higham(2002), p.334f - simple example
A <- matrix(1, 3, 3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A[c("mat", "normF")]
stopifnot(all.equal(n.A$mat[1,2], 0.760689917),
          all.equal(n.A$normF, 0.52779033, tolerance=1e-9) )

set.seed(27)
```

```

m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(require("sfsmisc")) {
  m2 <- posdefify(m) # a simpler approach
  norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

## A longer example, extended from Jens' original,
## showing the effects of some of the options:

pr <- Matrix(c(1,      0.477, 0.644, 0.478, 0.651, 0.826,
               0.477, 1,      0.516, 0.233, 0.682, 0.75,
               0.644, 0.516, 1,      0.599, 0.581, 0.742,
               0.478, 0.233, 0.599, 1,      0.741, 0.8,
               0.651, 0.682, 0.581, 0.741, 1,      0.798,
               0.826, 0.75, 0.742, 0.8, 0.798, 1),
             nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.1 <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.1$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr) # still 2 iterations
ncr.1 <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.1 $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF)) # norm type does not matter at all in this example

## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently :
norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr - ncr.1$mat) # = 0.08746 / 0.08805

### 3) a real data example from a 'systemfit' model (3 eq.):
(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW) # "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) ## looking more closely {EV sorted decreasingly}:
tail(EV) # all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(require("sfsmisc")) {
  plot(pmax(1e-3, EV), EV2, type="o", log="xy", xaxt="n", yaxt="n")
  eaxis(1); eaxis(2)
}

```

```

ngeMatrix-class	<i>Class "ngeMatrix" of General Dense Nonzero-pattern Matrices</i>
-----------------	--

---

## Description

This is the class of general dense nonzero-pattern matrices, see [nMatrix](#).

## Slots

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix". Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#)); use, e.g., [showMethods](#)(class="ngeMatrix") for details.

## See Also

Non-general logical dense matrix classes such as [ntrMatrix](#), or [nsyMatrix](#); *sparse* logical classes such as [ngCMatrix](#).

## Examples

```

showClass("ngeMatrix")
## "lgeMatrix" is really more relevant

```

nMatrix-class

Class "nMatrix" of Non-zero Pattern Matrices

## Description

The `nMatrix` class is the virtual “mother” class of all *non-zero pattern* (or simply *pattern*) matrices in the **Matrix** package.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

## Methods

There is a bunch of coercion methods (for `as ( . )`), e.g.,

**coerce** signature(from = "matrix", to = "nMatrix"): Note that these coercions (must) coerce `NAs` to non-zero, hence conceptually `TRUE`. This is particularly important when `sparseMatrix` objects are coerced to "nMatrix" and hence to `nsparseMatrix`.

**coerce** signature(from = "dMatrix", to = "nMatrix"), and

**coerce** signature(from = "lMatrix", to = "nMatrix"): For dense matrices with `NAs`, these coercions are valid since **Matrix** version 1.2.0 (still with a `warning` or a `message` if "Matrix.warn", or "Matrix.verbose" `options` are set.)

**coerce** signature(from = "nMatrix", to = "matrix"): ...

**coerce** signature(from = "nMatrix", to = "dMatrix"): ...

**coerce** signature(from = "nMatrix", to = "lMatrix"): ...

— — —

Additional methods contain group methods, such as

**Ops** signature(e1 = "nMatrix", e2 = "...."),...

**Arith** signature(e1 = "nMatrix", e2 = "...."),...

**Compare** signature(e1 = "nMatrix", e2 = "...."),...

**Logic** signature(e1 = "nMatrix", e2 = "...."),...

**Summary** signature(x = "nMatrix", "...."),...

## See Also

The classes `lMatrix`, `nsparseMatrix`, and the mother class, `Matrix`.

## Examples

```
getClass("nMatrix")

L3 <- Matrix(upper.tri(diag(3)))
L3 # an "ltCMatrix"
as(L3, "nMatrix") # -> ntC*

## similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix") # currently "ngTMatrix"
```

nnzero

*The Number of Non-Zero Values of a Matrix*

## Description

Returns the number of non-zero values of a numeric-like R object, and in particular an object `x` inheriting from class `Matrix`.

## Usage

```
nnzero(x, na.counted = NA)
```

## Arguments

`x` an R object, typically inheriting from class `Matrix` or `numeric`.

`na.counted` a `logical` describing how `NA`s should be counted. There are three possible settings for `na.counted`:

**TRUE** `NA`s are counted as non-zero (since “they are not zero”).

**NA** (default) the result will be `NA` if there are `NA`’s in `x` (since “`NA`’s are not known, i.e., *may be* zero”).

**FALSE** `NA`s are *omitted* from `x` before the non-zero entries are counted.

For sparse matrices, you may often want to use `na.counted = TRUE`.

## Value

the number of non zero entries in `x` (typically `integer`).

Note that for a *symmetric* sparse matrix `S` (i.e., inheriting from class `symmetricMatrix`), `nnzero(S)` is typically *twice* the `length(S@x)`.

## Methods

`signature(x = "ANY")` the default method for non-`Matrix` class objects, simply counts the number 0s in `x`, counting `NA`’s depending on the `na.counted` argument, see above.

`signature(x = "denseMatrix")` conceptually the same as for traditional `matrix` objects, care has to be taken for `"symmetricMatrix"` objects.

`signature(x = "diagonalMatrix")`, **and** `signature(x = "indMatrix")` fast simple methods for these special `"sparseMatrix"` classes.

`signature(x = "sparseMatrix")` typically, the most interesting method, also carefully taking `"symmetricMatrix"` objects into account.

See Also

The `Matrix` class also has a `length` method; typically, `length(M)` is much larger than `nnzero(M)` for a sparse matrix `M`, and the latter is a better indication of the *size* of `M`.  
`drop0`, `zapsmall`.

Examples

```
m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "dgTMatrix"))
nnzero(mT)
(S <- crossprod(mT))
nnzero(S)
str(S) # slots are smaller than nnzero()
stopifnot(nnzero(S) == sum(as.matrix(S) != 0)) # failed earlier

data(KNex)
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
nnzero(M) # more relevant than length
## the above are also visible from
str(M)
```

---

norm	<i>Matrix Norms</i>
------	---------------------

---

Description

Computes a matrix norm of `x`, using Lapack for dense matrices. The norm can be the one norm, the infinity norm, the Frobenius norm, or the maximum modulus among elements of a matrix, as determined by the value of `type`.

Usage

```
norm(x, type, ...)
```

Arguments

- `x` a real or complex matrix.
- `type` A character indicating the type of norm desired.  
"O", "o" or "1" specifies the one norm, (maximum absolute column sum);  
"I" or "i" specifies the infinity norm (maximum absolute row sum);  
"F" or "f" specifies the Frobenius norm (the Euclidean norm of `x` treated as if it were a vector); and  
"M" or "m" specifies the maximum modulus of all the elements in `x`.  
The default is "O". Only the first character of `type[1]` is used.
- `...` further arguments passed to or from other methods.

## Details

For dense matrices, the methods eventually call the Lapack functions `dlange`, `dlansy`, `dlantr`, `zlange`, `zlansy`, and `zlantr`.

## Value

A numeric value of class `"norm"`, representing the quantity chosen according to `type`.

## References

Anderson, E., et al. (1994). *LAPACK User's Guide*, 2nd edition, SIAM, Philadelphia.

## See Also

`onenormest()`, an *approximate* randomized estimate of the 1-norm condition number, efficient for large sparse matrices.

## Examples

```
x <- Hilbert(9)
norm(x, "1")
norm(x, "I")
norm(x, "F")
norm(x, "M")
```

---

nsparseMatrix-classes

*Sparse "pattern" Matrices*

---

## Description

The `nsparseMatrix` class is a virtual class of sparse “*pattern*” matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (`TsparseMatrix`, subclasses `ngTMatrix`, `nsTMatrix`, and `ntTMatrix` which really contain pairs, not triplets) or in compressed column-oriented form (class `CsparseMatrix`, subclasses `ngCMatrix`, `nsCMatrix`, and `ntCMatrix`) or—rarely—in compressed row-oriented form (class `RsparseMatrix`, subclasses `ngRMatrix`, `nsRMatrix`, and `ntRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

## Objects from the Class

Objects can be created by calls of the form `new("ngCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

## Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- Dim:** Object of class "integer" - the dimensions of the matrix.

## Methods

- coerce** signature(from = "dgCMatrix", to = "ngCMatrix"), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are coerced to TRUE, not FALSE, see the example.
- t** signature(x = "ngCMatrix"): returns the transpose of x
- which** signature(x = "lsparseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

## See Also

the class [dgCMatrix](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
## ``extract the nonzero-pattern of (m) into an nMatrix``:
nm <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"
str(nm) # no 'x' slot
nnm <- !nm      # no longer sparse
(nnm <- as(nnm, "sparseMatrix"))# "lgCMatrix"
## consistency check:
stopifnot(xor(as( nm, "matrix"),
               as(nnm, "matrix"))

## low-level way of adding "non-structural zeros" :
nnm@x[2:4] <- c(FALSE,NA,NA)
nnm
as(nnm, "nMatrix") # NAs *and* non-structural 0 |---> 'TRUE'

data(KNex)
nnm <- as(KNex $ mm, "ngCMatrix")
str(xlx <- crossprod(nnm))# "nsCMatrix"
stopifnot(isSymmetric(xlx))
image(xlx, main=paste("crossprod(nnm) : Sparse", class(xlx)))
```

---

 nsyMatrix-class      *Symmetric Dense Nonzero-Pattern Matrices*

---

## Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas

"nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use [showClass](#)("nsyMatrix"), e.g., for details.

## Methods

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods](#)(class="dsyMatrix") for details.

## See Also

[ngeMatrix](#), [Matrix](#), [t](#)

## Examples

```
(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA,FALSE,FALSE), 2,2)) # logical dense (ltr)
(sM <- M2 & t(M2))          # "lge"
class(sM <- as(sM, "nMatrix")) # -> "nge"
      (sM <- as(sM, "nsyMatrix")) # -> "nsy"
str ( sM <- as(sM, "nspMatrix")) # -> "nsp": packed symmetric
```

---

ntrMatrix-class      *Triangular Dense Logical Matrices*

---

**Description**

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

"ntrMatrix" extends class "ngeMatrix", directly, whereas  
 "ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, *indirectly*, use [showClass](#) ("nsyMatrix"), e.g., for details.

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods](#)(class="nsyMatrix") for details.

**See Also**

Classes [ngeMatrix](#), [Matrix](#); function [t](#)

**Examples**

```
showClass("ntrMatrix")

str(new("ntpMatrix"))
(nutr <- as(upper.tri(matrix(,4,4)), "ntrMatrix"))
str(nutp <- as(nutr, "ntpMatrix"))# packed matrix: only 10 = (4+1)*4/2 entries
!nutp ## the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(nutp, as(!!nutp, "ntpMatrix")))
```

---

number-class	<i>Class "number" of Possibly Complex Numbers</i>
--------------	---

---

### Description

The class "number" is a virtual class, currently used for vectors of eigen values which can be "numeric" or "complex".

It is a simple class union ([setClassUnion](#)) of "numeric" and "complex".

### Objects from the Class

Since it is a virtual Class, no objects may be created from it.

### Examples

```
showClass("number")
stopifnot( is(li, "number"), is(pi, "number"), is(1:3, "number") )
```

---

pMatrix-class	<i>Permutation matrices</i>
---------------	-----------------------------

---

### Description

The "pMatrix" class is the class of permutation matrices, stored as 1-based integer permutation vectors.

Matrix (vector) multiplication with permutation matrices is equivalent to row or column permutation, and is implemented that way in the **Matrix** package, see the ‘Details’ below.

### Details

Matrix multiplication with permutation matrices is equivalent to row or column permutation. Here are the four different cases for an arbitrary matrix  $M$  and a permutation matrix  $P$  (where we assume matching dimensions):

$$\begin{aligned}
 MP &= M \%*\% P &= M[, i(p)] \\
 PM &= P \%*\% M &= M[ p, ] \\
 P'M &= \text{crossprod}(P, M) (\approx t(P) \%*\% M) &= M[i(p), ] \\
 MP' &= \text{tcrossprod}(M, P) (\approx M \%*\% t(P)) &= M[ , p ]
 \end{aligned}$$

where  $p$  is the “permutation vector” corresponding to the permutation matrix  $P$  (see first note), and  $i(p)$  is short for [invPerm](#)( $p$ ).

Also one could argue that these are really only two cases if you take into account that inversion ([solve](#)) and transposition ([t](#)) are the same for permutation matrices  $P$ .

### Objects from the Class

Objects can be created by calls of the form `new("pMatrix", ...)` or by coercion from an integer permutation vector, see below.

**Slots**

**perm:** An integer, 1-based permutation vector, i.e. an integer vector of length `Dim[1]` whose elements form a permutation of `1:Dim[1]`.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of equal, non-negative integers.

**Dimnames:** list of length two; each component containing NULL or a [character](#) vector length equal the corresponding `Dim` element.

**Extends**

Class "[indMatrix](#)", directly.

**Methods**

`%%` signature(`x = "matrix"`, `y = "pMatrix"`) and other signatures (use `showMethods("%*", class="pMatrix")`): ...

**coerce** signature(`from = "integer"`, `to = "pMatrix"`): This enables typical "pMatrix" construction, given a permutation vector of `1:n`, see the first example.

**coerce** signature(`from = "numeric"`, `to = "pMatrix"`): a user convenience, to allow as(`perm`, "pMatrix") for numeric `perm` with integer values.

**coerce** signature(`from = "pMatrix"`, `to = "matrix"`): coercion to a traditional FALSE/TRUE [matrix](#) of [mode](#) logical. (in earlier version of **Matrix**, it resulted in a 0/1-integer matrix; logical makes slightly more sense, corresponding better to the "natural" [sparseMatrix](#) counterpart, "[ngTMatrix](#)".)

**coerce** signature(`from = "pMatrix"`, `to = "ngTMatrix"`): coercion to sparse logical matrix of class [ngTMatrix](#).

**determinant** signature(`x = "pMatrix"`, `logarithm="logical"`): Since permutation matrices are orthogonal, the determinant must be +1 or -1. In fact, it is exactly the *sign of the permutation*.

**solve** signature(`a = "pMatrix"`, `b = "missing"`): return the inverse permutation matrix; note that `solve(P)` is identical to `t(P)` for permutation matrices. See [solve-methods](#) for other methods.

**t** signature(`x = "pMatrix"`): return the transpose of the permutation matrix (which is also the inverse of the permutation matrix).

**Note**

For every permutation matrix `P`, there is a corresponding permutation vector `p` (of indices, `1:n`), and these are related by

```
P <- as(p, "pMatrix")
p <- P@perm
```

see also the 'Examples'.

"Row-indexing" a permutation matrix typically returns an "[indMatrix](#)". See "[indMatrix](#)" for all other subsetting/indexing and subassignment (`A[. .] <- v`) operations.

**See Also**

[invPerm](#)(`p`) computes the inverse permutation of an integer (index) vector `p`.

**Examples**

```

(pm1 <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pm1) # is the same as
solve(pm1)
pm1 %*% t(pm1) # check that the transpose is the inverse
stopifnot(all(diag(3) == as(pm1 %*% t(pm1), "matrix")),
           is.logical(as(pm1, "matrix")))

set.seed(11)
## random permutation matrix :
(pl0 <- as(sample(10), "pMatrix"))

## Permute rows / columns of a numeric matrix :
(mm <- round(array(rnorm(3 * 3), c(3, 3)), 2))
mm %*% pm1
pm1 %*% mm
try(as(as.integer(c(3,3,1)), "pMatrix"))# Error: not a permutation

as(pm1, "ngTMatrix")
pl0[1:7, 1:4] # gives an "ngTMatrix" (most economic!)

## row-indexing of a <pMatrix> keeps it as an <indMatrix>:
pl0[1:3, ]

```

---

printSpMatrix

---

*Format and Print Sparse Matrices Flexibly*

---

**Description**

Format and print sparse matrices flexibly. These are the “workhorses” used by the [format](#), [show](#) and [print](#) methods for sparse matrices. If `x` is large, `printSpMatrix2(x)` calls `printSpMatrix()` twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when `x` is too wide.

`printSpMatrix()` basically prints the result of `formatSpMatrix()`.

**Usage**

```

formatSpMatrix(x, digits = NULL, maxp = 1e9,
               cld = getClassDef(class(x)), zero.print = ".",
               col.names, note.dropping.colnames = TRUE, uniDiag = TRUE,
               align = c("fancy", "right"))

printSpMatrix(x, digits = NULL, maxp = getOption("max.print"),
              cld = getClassDef(class(x)),
              zero.print = ".", col.names, note.dropping.colnames = TRUE,
              uniDiag = TRUE, col.trailer = "",
              align = c("fancy", "right"))

printSpMatrix2(x, digits = NULL, maxp = getOption("max.print"),
               zero.print = ".", col.names, note.dropping.colnames = TRUE,
               uniDiag = TRUE, suppRows = NULL, suppCols = NULL,
               col.trailer = if(suppCols) "....." else "",

```

```
align = c("fancy", "right"),
width = getOption("width"), fitWidth = TRUE)
```

## Arguments

<code>x</code>	an R object inheriting from class <code>sparseMatrix</code> .
<code>digits</code>	significant digits to use for printing, see <code>print.default</code> , the default, <code>NULL</code> , corresponds to using <code>getOption("digits")</code> .
<code>maxp</code>	integer, default from <code>options(max.print)</code> , influences how many entries of large matrices are printed at all.
<code>cld</code>	the class definition of <code>x</code> ; must be equivalent to <code>getClassDef(class(x))</code> and exists mainly for possible speedup.
<code>zero.print</code>	character which should be printed for <i>structural</i> zeroes. The default <code>"."</code> may occasionally be replaced by <code>" "</code> (blank); using <code>"0"</code> would look almost like <code>print()</code> ing of non-sparse matrices.
<code>col.names</code>	logical or string specifying if and how column names of <code>x</code> should be printed, possibly abbreviated. The default is taken from <code>options("sparse.colnames")</code> if that is set, otherwise <code>FALSE</code> unless there are less than ten columns. When <code>TRUE</code> the full column names are printed. When <code>col.names</code> is a string beginning with <code>"abb"</code> or <code>"sub"</code> and ending with an integer <code>n</code> (i.e., of the form <code>"abb... &lt;n&gt;"</code> ), the column names are <code>abbreviate()</code> d or <code>substring()</code> ed to (target) length <code>n</code> , see the examples.
<code>note.dropping.colnames</code>	logical specifying, when <code>col.names</code> is <code>FALSE</code> if the dropping of the column names should be noted, <code>TRUE</code> by default.
<code>uniDiag</code>	logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as <code>"I"</code> instead of <code>"1"</code> (to emphasize that the 1's are "structural").
<code>col.trailer</code>	a string to be appended to the right of each column; this is typically made use of by <code>show(&lt;sparseMatrix&gt;)</code> only, when suppressing columns.
<code>suppRows, suppCols</code>	logicals or <code>NULL</code> , for <code>printSpMatrix2()</code> specifying if rows or columns should be suppressed in printing. If <code>NULL</code> , sensible defaults are determined from <code>dim(x)</code> and <code>options(c("width", "max.print"))</code> . Setting both to <code>FALSE</code> may be a very bad idea.
<code>align</code>	a string specifying how the <code>zero.print</code> codes should be aligned, i.e., padded as strings. The default, <code>"fancy"</code> , takes some effort to align the typical <code>zero.print = "."</code> with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas <code>align = "right"</code> just makes use of <code>print(*, right = TRUE)</code> .
<code>width</code>	number, a positive integer, indicating the approximately desired (line) width of the output, see also <code>fitWidth</code> .
<code>fitWidth</code>	logical indicating if some effort should be made to match the desired <code>width</code> or temporarily enlarge that if deemed necessary.

## Details

**formatSpMatrix:** If `x` is large, only the first rows making up the approximately first `maxp` entries is used, otherwise all of `x`. `.formatSparseSimple()` is applied to (a dense version of)

the matrix. Then, `formatSparseM` is used, unless in trivial cases or for sparse matrices without `x` slot.

### Value

```
formatSpMatrix()
    returns a character matrix with possibly empty column names, depending on
    col.names etc, see above.
printSpMatrix*()
    return x invisibly, see invisible.
```

### Author(s)

Martin Maechler

### See Also

the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

### Examples

```
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## <==> show(X) <==> print(X)
t(X) ## shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12], "c", sep=".")),
        "sparseMatrix")
X2
## less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

## Possibilities with column names printing:
t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = "", col.names="abbr. 1")
print(t(X2), zero.print = "-", col.names="substring 2")
```

### Description

The "Matrix" package provides methods for the QR decomposition of special classes of matrices. There is a generic function which uses `qr` as default, but methods defined in this package can take extra arguments. In particular there is an option for determining a fill-reducing permutation of the columns of a sparse, rectangular matrix.

**Usage**

```
qr(x, ...)
qrR(qr, complete=FALSE, backPermute=TRUE, row.names = TRUE)
```

**Arguments**

<code>x</code>	a numeric or complex matrix whose QR decomposition is to be computed. Logical matrices are coerced to numeric.
<code>qr</code>	a QR decomposition of the type computed by <code>qr</code> .
<code>complete</code>	logical indicating whether the $R$ matrix is to be completed by binding zero-value rows beneath the square upper triangle.
<code>backPermute</code>	logical indicating if the rows of the $R$ matrix should be back permuted such that <code>qrR()</code> 's result can be used directly to reconstruct the original matrix $X$ .
<code>row.names</code>	logical indicating if <code>rownames</code> should be propagated to the result.
<code>...</code>	further arguments passed to or from other methods

**Methods**

`x = "dgCMatrix"` QR decomposition of a general sparse double-precision matrix with `nrow(x) >= ncol(x)`. Returns an object of class `"sparseQR"`.

`x = "sparseMatrix"` works via `"dgCMatrix"`.

**See Also**

`qr`; then, the class documentations, mainly `sparseQR`, and also `dgCMatrix`.

**Examples**

```
##----- example of pivoting -- from base' qraux.Rd -----
X <- Matrix(cbind(int = 1,
                  b1=rep(1:0, each=3), b2=rep(0:1, each=3),

  as.numeric(X[,nna] %*% cfqx[nna])))
## FIXME: do these make *any* sense? --- should give warnings !
qr.coef(qX, y)
qr.coef(qX, Y)
rm(m)

```

rankMatrix

*Rank of a Matrix***Description**

Compute ‘the’ matrix rank, a well-defined functional in theory, somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

**Usage**

```
rankMatrix(x, tol = NULL,
  method = c("tolNorm2", "qr.R", "qrLINPACK", "qr",
    "useGrad", "maybeGrad"),
  sval = svd(x, 0, 0)$d, warn.t = TRUE)
```

**Arguments**

<code>x</code>	numeric matrix, of dimension $n \times m$ , say.
<code>tol</code>	nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on <code>method</code> ; by default, <code>max(dim(x)) * .Machine\$double.eps</code> is according to Matlab’s default (for its only method which is our <code>method="tolNorm2"</code> ).
<code>method</code>	<p>a character string specifying the computational method for the rank, can be abbreviated:</p> <p><code>"tolNorm2"</code>: the number of singular values <math>\geq \text{tol} * \max(\text{sval})</math>;</p> <p><code>"qrLINPACK"</code>: for a dense matrix, this is the rank of <code>qr(x, tol, LAPACK=FALSE)</code> (which is <code>qr(...)\$rank</code>); This (“qr*”, dense) version used to be <i>the</i> recommended way to compute a matrix rank for a while in the past. For sparse <code>x</code>, this is equivalent to <code>"qr.R"</code>.</p> <p><code>"qr.R"</code>: this is the rank of triangular matrix <math>R</math>, where <code>qr()</code> uses LAPACK or a “sparseQR” method (see <a href="#">qr-methods</a>) to compute the decomposition <math>QR</math>. The rank of <math>R</math> is then defined as the number of “non-zero” diagonal entries <math>d_i</math> of <math>R</math>, and “non-zero”s fulfill <math> d_i  \geq \text{tol} \cdot \max( d_i )</math>.</p> <p><code>"qr"</code>: is for back compatibility; for dense <code>x</code>, it corresponds to <code>"qrLINPACK"</code>, whereas for sparse <code>x</code>, it uses <code>"qr.R"</code>. For all the “qr*” methods, singular values <code>sval</code> are not used, which may be crucially important for a large sparse matrix <code>x</code>, as in that case, when <code>sval</code> is not specified, the default, computing <code>svd()</code> currently coerces <code>x</code> to a dense matrix.</p> <p><code>"useGrad"</code>: considering the “gradient” of the (decreasing) singular values, the index of the <i>smallest</i> gap.</p> <p><code>"maybeGrad"</code>: choosing method <code>"useGrad"</code> only when that seems <i>reasonable</i>; otherwise using <code>"tolNorm2"</code>.</p>
<code>sval</code>	numeric vector of non-increasing singular values of <code>x</code> ; typically unspecified and computed from <code>x</code> when needed, i.e., unless <code>method = "qr"</code> .
<code>warn.t</code>	logical indicating if <code>rankMatrix()</code> should warn when it needs <code>t(x)</code> instead of <code>x</code> . Currently, for <code>method = "qr"</code> only, gives a warning by default because the caller often could have passed <code>t(x)</code> directly, more efficiently.

**Value**

positive integer in `1:min(dim(x))`, with attributes detailing the method used.

**Note**

For large sparse matrices `x`, unless you can specify `sval` yourself, currently `method = "qr"` may be the only feasible one, as the others need `sval` and call `svd()` which currently coerces `x` to a `denseMatrix` which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse `x`, `method = "qr"`, all non-strictly zero diagonal entries  $d_i$  where counted, up to including **Matrix** version 1.1-0, i.e., that method implicitly used `tol = 0`, see also the `seed(42)` example below.

**Author(s)**

Martin Maechler; for the “\*Grad” methods, building on suggestions by Ravi Varadhan.

**See Also**

[qr](#), [svd](#).

**Examples**

```
rankMatrix(cbind(1, 0, 1:3)) # 2

(meths <- eval(formals(rankMatrix)$method))

## a "border" case:
H12 <- Hilbert(12)
rankMatrix(H12, tol = 1e-20) # 12; but 11 with default method & tol.
sapply(meths, function(.m.) rankMatrix(H12, method = .m.))
## tolNorm2    qr    qr.R    qrLINPACK    useGrad maybeGrad
##          11    12         11          12         11         11
## The meaning of 'tol' for method="qrLINPACK" and *dense* x is not entirely "scale free"
rMQL <- function(ex, M) rankMatrix(M, method="qrLINPACK",tol = 10^-ex)
rMQR <- function(ex, M) rankMatrix(M, method="qr.R",      tol = 10^-ex)
sapply(5:15, rMQL, M = H12) # result is platform dependent
## 7 7 8 10 10 11 11 11 12 12 12 {x86_64}
sapply(5:15, rMQL, M = 1000 * H12) # not identical unfortunately
## 7 7 8 10 11 11 12 12 12 12 12
sapply(5:15, rMQR, M = H12)
## 5 6 7 8 8 9 9 10 10 11 11
sapply(5:15, rMQR, M = 1000 * H12) # the *same*

## "sparse" case:
M15 <- kronecker(diag(x=c(100,1,10)), Hilbert(5))
sapply(meths, function(.m.) rankMatrix(M15, method = .m.))
#--> all 15, but 'useGrad' has 14.

## "large" sparse
n <- 250000; p <- 33; nnz <- 10000
L <- sparseMatrix(i = sample.int(n, nnz, replace=TRUE),
                  j = sample.int(p, nnz, replace=TRUE), x = rnorm(nnz))
(st1 <- system.time(r1 <- rankMatrix(L))) # warning + ~1.5 sec
(st2 <- system.time(r2 <- rankMatrix(L, method = "qr"))) # considerably faster!
r1[[1]] == print(r2[[1]]) ## --> ( 33 TRUE )

## another sparse-"qr" one, which ``failed'' till 2013-11-23:
set.seed(42)
f1 <- factor(sample(50, 1000, replace=TRUE))
f2 <- factor(sample(50, 1000, replace=TRUE))
f3 <- factor(sample(50, 1000, replace=TRUE))
rbind. <- if(getRversion() < "3.2.0") rBind else rbind
D <- t(do.call(rbind., lapply(list(f1,f2,f3), as, 'sparseMatrix'))))
dim(D); nnzero(D) ## 1000 x 150 // 3000 non-zeros (= 2%)
stopifnot(rankMatrix(D, method='qr') == 148,
           rankMatrix(crossprod(D),method='qr') == 148)
```

## Description

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by `showMethods(rcond)`.

## Usage

```
rcond(x, norm, ...)
```

```
## S4 method for signature 'sparseMatrix,character'
rcond(x, norm, useInv=FALSE, ...)
```

## Arguments

<code>x</code>	an R object that inherits from the <code>Matrix</code> class.
<code>norm</code>	character string indicating the type of norm to be used in the estimate. The default is "O" for the 1-norm ("O" is equivalent to "1"). For sparse matrices, when <code>useInv=TRUE</code> , <code>norm</code> can be any of the kinds allowed for <code>norm</code> ; otherwise, the other possible value is "I" for the infinity norm, see also <code>norm</code> .
<code>useInv</code>	logical (or "Matrix" containing <code>solve(x)</code> ). If not false, compute the reciprocal condition number as $1/(\ x\  \cdot \ x^{-1}\ )$ , where $x^{-1}$ is the inverse of $x$ , <code>solve(x)</code> . This may be an efficient alternative (only) in situations where <code>solve(x)</code> is fast (or known), e.g., for (very) sparse or triangular matrices. Note that the <i>result</i> may differ depending on <code>useInv</code> , as per default, when it is false, an <i>approximation</i> is computed.
<code>...</code>	further arguments passed to or from other methods.

## Value

An estimate of the reciprocal condition number of `x`.

## BACKGROUND

The condition number of a regular (square) matrix is the product of the `norm` of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices  $A$ ) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$

Whenever `x` is *not* a square matrix, in our method definitions, this is typically computed via `rcond(qr.R(qr(X)), ...)` where  $X$  is `x` or `t(x)`.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

`rcond()` computes the *reciprocal* condition number  $1/\kappa$  with values in  $[0, 1]$  and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka "singular").

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

## References

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

## See Also

`norm`, `kappa()` from package **base** computes an *approximate* condition number of a “traditional” matrix, even non-square ones, with respect to the  $p = 2$  (Euclidean) `norm.solve`.

`condest`, a newer *approximate* estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

## Examples

```
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9)) # should be about 9.1e-13

## For non-square matrices:
rcond(x1 <- cbind(1,1:10))# 0.05278
rcond(x2 <- cbind(x1, 2:11))# practically 0, since x2 does not have full rank

## sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

## Large sparse example -----
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
  system.time(r <- rcond(M3))
## whereas this is *fast* even though it computes solve(M3)
system.time(r. <- rcond(M3, useInv=TRUE))
if(interactive()) ## the values are not the same
  c(r, r.) # 0.05555 0.013888
## for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
  function(N) rcond(M3, norm=N, useInv=TRUE)))
```

**Description**

`rep2abI(x, times)` conceptually computes `rep.int(x, times)` but with an `abIndex` class result.

**Usage**

```
rep2abI(x, times)
```

**Arguments**

<code>x</code>	numeric vector
<code>times</code>	integer (valued) scalar: the number of repetitions

**Value**

a vector of `class abIndex`

**See Also**

`rep.int()`, the base function; `abIseq`, `abIndex`.

**Examples**

```
(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
  rep(2:7, 4)))
```

---

replValue-class	<i>Virtual Class "replValue" - Simple Class for subassignment Values</i>
-----------------	--

---

**Description**

The class "replValue" is a virtual class used for values in signatures for sub-assignment of "Matrix" matrices.

In fact, it is a simple class union (`setClassUnion`) of "numeric" and "logical" (and maybe "complex" in the future).

**Objects from the Class**

Since it is a virtual Class, no objects may be created from it.

**See Also**

`Subassign-methods`, also for examples.

**Examples**

```
showClass("replValue")
```

---

rleDiff-class

Class "rleDiff" of rle(diff(.)) Stored Vectors

---

## Description

Class "rleDiff" is for compactly storing long vectors which mainly consist of *linear* stretches. For such a vector `x`, `diff(x)` consists of *constant* stretches and is hence well compressable via `rle()`.

## Objects from the Class

Objects can be created by calls of the form `new("rleDiff", ...)`.

Currently experimental, see below.

## Slots

**first:** A single number (of class "numLike", a class union of "numeric" and "logical").

**rle:** Object of class "rle", basically a `list` with components "lengths" and "values", see `rle()`. As this is used to encode potentially huge index vectors, lengths may be of type `double` here.

## Methods

There is a simple `show` method only.

## Note

This is currently an *experimental* auxiliary class for the class `abIndex`, see there.

## See Also

`rle`, `abIndex`.

## Examples

```
showClass("rleDiff")

ab <- c(abIseq(2, 100), abIseq(20, -2))
ab@rleD # is "rleDiff"
```

---

rsparsematrix      *Random Sparse Matrix*

---

## Description

Generate a Random Sparse Matrix Efficiently.

## Usage

```
rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
              symmetric = FALSE,
              rand.x = function(n) signif(rnorm(nnz), 2), ...)
```

## Arguments

nrow, ncol	number of rows and columns, i.e., the matrix dimension ( <code>dim</code> ).
density	optional number in $[0, 1]$ , the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for <code>nnz</code> , otherwise <code>nnz</code> needs to be specified.
nnz	number of non-zero entries, for a sparse matrix typically considerably smaller than <code>nrow*ncol</code> . Must be specified if <code>density</code> is not.
symmetric	logical indicating if result should be a matrix of class <code>symmetricMatrix</code> . Note that in the symmetric case, <code>nnz</code> denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.
rand.x	<code>NULL</code> or the random number generator for the <code>x</code> slot, a <code>function</code> such that <code>rand.x(n)</code> generates a numeric vector of length <code>n</code> . Typical examples are <code>rand.x = rnorm</code> , or <code>rand.x = runif</code> ; the default is nice for didactical purposes.
...	optionally further arguments passed to <code>sparseMatrix()</code> , notably <code>giveCsparse</code> .

## Details

The algorithm first samples “encoded”  $(i, j)$ s without replacement, via one dimensional indices, if not symmetric `sample.int(nrow*ncol, nnz)`, then—if `rand.x` is not `NULL`—gets `x <- rand.x(nnz)` and calls `sparseMatrix(i=i, j=j, x=x, ...)`. When `rand.x=NULL`, `sparseMatrix(i=i, j=j, ...)` will return a pattern matrix (i.e., inheriting from `nsparseMatrix`).

## Value

a `sparseMatrix`, say `M` of dimension  $(nrow, ncol)$ , i.e., with `dim(M) == c(nrow, ncol)`, if `symmetric` is not true, with `nzM <- nnzero(M)` fulfilling `nzM <= nnz` and typically, `nzM == nnz`.

## Author(s)

Martin Maechler

**Examples**

```

set.seed(17) # to be reproducible
M <- rsparsematrix(8, 12, nnz = 30) # small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, rand.x = runif)
summary(M1)

## a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
nnzero(S9) # ~ 20: as 'nnz' only counts one "triangle"

## a random patter*n* aka boolean Matrix (no 'x' slot):
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))

## a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, giveCsparse=FALSE)
head(T2)

```

---

RsparseMatrix-class

*Class "RsparseMatrix" of Sparse Matrices in Column-compressed Form*

---

**Description**

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("RsparseMatrix")` for its subclasses.

**Slots**

**j**: Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p**: Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**Dim, Dimnames**: inherited from the superclass, see [sparseMatrix](#).

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

**Methods**

Only **few** methods are defined currently on purpose, since we rather use the [CsparseMatrix](#) in **Matrix**. Recently, more methods were added but *beware* that these typically do *not* return "RsparseMatrix" results, but rather Csparse\* or Tsparse\* ones.

```

t signature(x = "RsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "CsparseMatrix"): ...
coerce signature(from = "RsparseMatrix", to = "TsparseMatrix"): ...

```

**See Also**

its superclass, [sparseMatrix](#), and, e.g., class [dgRMatrix](#) for the links to other classes.

**Examples**

```
showClass("RsparseMatrix")
```

---

 Schur

*Schur Decomposition of a Matrix*

---

**Description**

Computes the Schur decomposition and eigenvalues of a square matrix; see the BACKGROUND information below.

**Usage**

```
Schur(x, vectors, ...)
```

**Arguments**

<code>x</code>	numeric square Matrix (inheriting from class "Matrix") or traditional <a href="#">matrix</a> . Missing values (NAs) are not allowed.
<code>vectors</code>	logical. When TRUE (the default), the Schur vectors are computed, and the result is a proper <a href="#">MatrixFactorization</a> of class <a href="#">Schur</a> .
<code>...</code>	further arguments passed to or from other methods.

**Details**

Based on the Lapack subroutine dgees.

**Value**

If `vectors` are TRUE, as per default: If `x` is a [Matrix](#) an object of class [Schur](#), otherwise, for a traditional [matrix](#) `x`, a [list](#) with components `T`, `Q`, and `EValues`.

If `vectors` are FALSE, a list with components

<code>T</code>	the upper quasi-triangular (square) matrix of the Schur decomposition.
<code>EValues</code>	the vector of <a href="#">numeric</a> or <a href="#">complex</a> eigen values of $T$ or $A$ .

**BACKGROUND**

If  $A$  is a square matrix, then  $A = Q T^t(Q)$ , where  $Q$  is orthogonal, and  $T$  is upper block-triangular (nearly triangular with either 1 by 1 or 2 by 2 blocks on the diagonal) where the 2 by 2 blocks correspond to (non-real) complex eigenvalues. The eigenvalues of  $A$  are the same as those of  $T$ , which are easy to compute. The Schur form is used most often for computing non-symmetric eigenvalue decompositions, and for computing functions of matrices such as matrix exponentials.

**References**

Anderson, E., et al. (1994). *LAPACK User's Guide*, 2nd edition, SIAM, Philadelphia.

## Examples

```
Schur(Hilbert(9)) # Schur factorization (real eigenvalues)

(A <- Matrix(round(rnorm(5*5, sd = 100)), nrow = 5))
(Sch.A <- Schur(A))

eTA <- eigen(Sch.A@T)
str(SchA <- Schur(A, vectors=FALSE)) # no 'T' ==> simple list
stopifnot(all.equal(eTA$values, eigen(A)$values, tolerance = 1e-13),
  all.equal(eTA$values,
    local({z <- Sch.A@EValues
      z[order(Mod(z), decreasing=TRUE)]}), tolerance = 1e-13),
  identical(SchA$T, Sch.A@T),
  identical(SchA$EValues, Sch.A@EValues))

## For the faint of heart, we provide Schur() also for traditional matrices:

a.m <- function(M) unname(as(M, "matrix"))
a <- a.m(A)
Sch.a <- Schur(a)
stopifnot(identical(Sch.a, list(Q = a.m(Sch.A @ Q),
  T = a.m(Sch.A @ T),
  EValues = Sch.A@EValues)),
  all.equal(a, with(Sch.a, Q %*% T %*% t(Q))))
)
```

---

Schur-class

*Class "Schur" of Schur Matrix Factorizations*

---

## Description

Class "Schur" is the class of Schur matrix factorizations. These are a generalization of eigen value (or “spectral”) decompositions for general (possibly asymmetric) square matrices, see the [Schur\(\)](#) function.

## Objects from the Class

Objects of class "Schur" are typically created by [Schur\(\)](#).

## Slots

"Schur" has slots

**T:** Upper Block-triangular [Matrix](#) object.

**Q:** Square *orthogonal* "Matrix".

**EValues:** numeric or complex vector of eigenvalues of T.

**Dim:** the matrix dimension: equal to `c(n,n)` of class "integer".

## Extends

Class "[MatrixFactorization](#)", directly.

**See Also**

`Schur()` for object creation; [MatrixFactorization](#).

**Examples**

```
showClass("Schur")
Schur(M <- Matrix(c(1:7, 10:2), 4,4))
## Trivial, of course:
str(Schur(Diagonal(5)))

## for more examples, see Schur()
```

---

solve-methods

*Methods in Package Matrix for Function solve()*

---

**Description**

Methods for function `solve` to solve a linear system of equations, or equivalently, solve for  $X$  in

$$AX = B$$

where  $A$  is a square matrix, and  $X$ ,  $B$  are matrices or vectors (which are treated as 1-column matrices), and the R syntax is

```
X <- solve(A,B)
```

In `solve(a,b)` in the **Matrix** package,  $a$  may also be a [MatrixFactorization](#) instead of directly a matrix.

**Usage**

```
## S4 method for signature 'CHMfactor,ddenseMatrix'
solve(a, b,
      system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)

## S4 method for signature 'dgCMatrix,matrix'
solve(a, b, sparse = FALSE, tol = .Machine$double.eps, ...)

      solve(a, b, ...) ## *the* two-argument version, almost always preferred to
# solve(a)           ## the *rarely* needed one-argument version
```

**Arguments**

<code>a</code>	a square numeric matrix, $A$ , typically of one of the classes in <b>Matrix</b> . Logical matrices are coerced to corresponding numeric ones.
<code>b</code>	numeric vector or matrix (dense or sparse) as RHS of the linear system $Ax = b$ .
<code>system</code>	only if <code>a</code> is a <a href="#">CHMfactor</a> : character string indicating the kind of linear system to be solved, see below. Note that the default, "A", does <i>not</i> solve the triangular system (but "L" does).

sparse	only when a is a <code>sparseMatrix</code> , i.e., typically a <code>dgCMatrix</code> : logical specifying if the result should be a (formally) sparse matrix.
tol	only used when a is sparse, in the <code>isSymmetric(a, tol=*)</code> test, where that applies.
...	potentially further arguments to the methods.

## Methods

`signature(a = "ANY", b = "ANY")` is simply the **base** package's S3 generic `solve`.

`signature(a = "CHMfactor", b = "....")`, `system=*` The `solve` methods for a `"CHMfactor"` object take an optional third argument `system` whose value can be one of the character strings "A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P" or "Pt". This argument describes the system to be solved. The default, "A", is to solve  $Ax = b$  for  $x$  where A is sparse, positive-definite matrix that was factored to produce a. Analogously, `system = "L"` returns the solution  $x$ , of  $Lx = b$ ; similarly, for all system codes **but** "P" and "Pt" where, e.g., `x <- solve(a, b, system="P")` is equivalent to `x <- P %*% b`.

If b is a `sparseMatrix`, `system` is used as above the corresponding sparse CHOLMOD algorithm is called.

`signature(a = "ddenseMatrix", b = "....")` (for all b) work via `as(a, "dgeMatrix")`, using the its methods, see below.

`signature(a = "denseLU", b = "missing")` basically computes uses triangular forward- and back-solve.

`signature(a = "dgCMatrix", b = "matrix")` ,and

`signature(a = "dgCMatrix", b = "ddenseMatrix")` with extra argument list `( sparse = FALSE, tol = .Machine$double.eps )` : Uses the sparse `lu(a)` decomposition (which is cached in a's `factor` slot). By default, `sparse=FALSE`, returns a `denseMatrix`, since  $U^{-1}L^{-1}B$  may not be sparse at all, even when  $L$  and  $U$  are.

If `sparse=TRUE`, returns a `sparseMatrix` (which may not be very sparse at all, even if a was sparse).

`signature(a = "dgCMatrix", b = "dsparseMatrix")` ,and

`signature(a = "dgCMatrix", b = "missing")` with extra argument list `( sparse=FALSE, tol = .Machine$double.eps )` : Checks if a is symmetric, and in that case, coerces it to `"symmetricMatrix"`, and then computes a *sparse* solution via sparse Cholesky factorization, independently of the `sparse` argument. If a is not symmetric, the sparse `lu` decomposition is used and the result will be sparse or dense, depending on the `sparse` argument, exactly as for the above (`b = "ddenseMatrix"`) case.

`signature(a = "dgeMatrix", b = ".....")` solve the system via internal LU, calling LAPACK routines `dgetri` or `dgetrs`.

`signature(a = "diagonalMatrix", b = "matrix")` and other bs: Of course this is trivially implemented, as  $D^{-1}$  is diagonal with entries  $1/D[i, i]$ .

`signature(a = "dpoMatrix", b = "....Matrix")` ,and

`signature(a = "dppMatrix", b = "....Matrix")` The Cholesky decomposition of a is calculated (if needed) while solving the system.

`signature(a = "dsCMatrix", b = "....")` All these methods first try Cholmod's Cholesky factorization; if that works, i.e., typically if a is positive semi-definite, it is made use of. Otherwise, the sparse LU decomposition is used as for the "general" matrices of class `"dgCMatrix"`.

signature(a = "dspMatrix", b = "....") ,and  
signature(a = "dsyMatrix", b = "....") all end up calling LAPACK routines  
dsptri, dspttrs, dsytrs and dsyttri.  
signature(a = "dtCMatrix", b = "CsparseMatrix") ,  
signature(a = "dtCMatrix", b = "dgeMatrix") , etc sparse triangular solve, in  
traditional S/R also known as [backsolve](#), or [forwardsolve](#). solve(a,b) is a  
[sparseMatrix](#) if b is, and hence a [denseMatrix](#) otherwise.  
signature(a = "dtrMatrix", b = "ddenseMatrix") ,and  
signature(a = "dtpMatrix", b = "matrix") , and similar b, including  
"missing", and "diagonalMatrix":  
all use LAPACK based versions of efficient triangular [backsolve](#), or [forwardsolve](#).  
signature(a = "Matrix", b = "diagonalMatrix") works via  
as(b, "CsparseMatrix").  
signature(a = "sparseQR", b = "ANY") simply uses [qr.coef](#)(a, b).  
signature(a = "pMatrix", b = ".....") these methods typically use  
[crossprod](#)(a,b), as the inverse of a permutation matrix is the same as its transpose.  
signature(a = "TsparseMatrix", b = "ANY") all work via  
as(a, "CsparseMatrix").

### Examples

```
## A close to symmetric example with "quite sparse" inverse:
n1 <- 7; n2 <- 3
dd <- data.frame(a = gl(n1,n2), b = gl(n2,1,n1*n2))# balanced 2-way
X <- sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
XXt <- tcrossprod(X)
diag(XXt) <- rep(c(0,0,1,0), length.out = nrow(XXt))

n <- nrow(ZZ <- kronecker(XXt, Diagonal(x=c(4,1))))
image(a <- 2*Diagonal(n) + ZZ %*% Diagonal(x=c(10, rep(1, n-1))))
isSymmetric(a) # FALSE
image(drop0(skewpart(a)))
image(ia0 <- solve(a)) # checker board, dense [but really, a is singular!]
try(solve(a, sparse=TRUE))##-> error [ TODO: assertError ]
ia. <- solve(a, sparse=TRUE, tol = 1e-19)##-> *no* error
if(R.version$sarch == "x86_64")
  ## Fails on 32-bit [Fedora 19, R 3.0.2] from Matrix 1.1-0 on [FIXME ??] only
  stopifnot(all.equal(as.matrix(ia.), as.matrix(ia0)))
a <- a + Diagonal(n)
iad <- solve(a)
ias <- solve(a, sparse=TRUE)
stopifnot(all.equal(as(ias,"denseMatrix"), iad, tolerance=1e-14))
I. <- iad %*% a ; image(I.)
I0 <- drop0(zapsmall(I.)); image(I0)
.I <- a %*% iad
.I0 <- drop0(zapsmall(.I))
stopifnot( all.equal(as(I0, "diagonalMatrix"), Diagonal(n)),
```

```
all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)) )
```

---

```
sparse.model.matrix
```

*Construct Sparse Design / Model Matrices*

---

## Description

Construct a sparse model or “design” matrix, from a formula and data frame (`sparse.model.matrix`) or a single factor (`fac2sparse`).

The `fac2[Ss]parse()` functions are utilities, also used internally in the principal user level function `sparse.model.matrix()`.

## Usage

```
sparse.model.matrix(object, data = environment(object),
  contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
  drop.unused.levels = FALSE, row.names = TRUE,
  verbose = FALSE, ...)
```

```
fac2sparse(from, to = c("d", "i", "l", "n", "z"),
  drop.unused.levels = TRUE, giveCsparse = TRUE)
fac2Sparse(from, to = c("d", "i", "l", "n", "z"),
  drop.unused.levels = TRUE, giveCsparse = TRUE,
  factorPatt12, contrasts.arg = NULL)
```

## Arguments

- |                    |  |
|--------------------|--|
| object             | an object of an appropriate class. For the default method, a model formula or terms object.  |
| data               | a data frame created with <code>model.frame</code> . If another sort of object, <code>model.frame</code> is called first.  |
| contrasts.arg      | <p><b>for</b> <code>sparse.model.matrix()</code>: A list, whose entries are contrasts suitable for input to the <code>contrasts</code> replacement function and whose names are the names of columns of data containing <code>factors</code>.</p> <p><b>for</b> <code>fac2Sparse()</code>: character string or <code>NULL</code> or (coercable to) <code>"sparseMatrix"</code>, specifying the contrasts to be applied to the factor levels.</p> |
| xlev               | to be used as argument of <code>model.frame</code> if data has no "terms" attribute.   |
| transpose          | logical indicating if the <i>transpose</i> should be returned; if the transposed is used anyway, setting <code>transpose = TRUE</code> is more efficient.  |
| drop.unused.levels | should factors have unused levels dropped? The default for <code>sparse.model.matrix</code> has been changed to <code>FALSE</code> , 2010-07, for compatibility with R's standard (dense) <code>model.matrix()</code> .  |
| row.names          | logical indicating if row names should be used.  |

verbose        logical or integer indicating if (and how much) progress output should be printed.  
 ...            further arguments passed to or from other methods.  
 from           (for `fac2sparse()`) a `factor`.  
 to             a character indicating the “kind” of sparse matrix to be returned. The default, "d" is for `double`.  
 giveCsparse   (for `fac2sparse()`) logical indicating if the result must be a `CsparseMatrix`.  
 factorPatt12   logical vector, say `fp`, of length two; when `fp[1]` is true, return “contrasted”  $t(X)$ ; when `fp[2]` is true, the original (“dummy”)  $t(X)$ , i.e, the result of `fac2sparse()`.

### Value

a sparse matrix, extending `CsparseMatrix` (for `fac2sparse()` if `giveCsparse` is true as per default; a `TsparseMatrix`, otherwise).

For `fac2Sparse()`, a `list` of length two, both components with the corresponding transposed model matrix, where the corresponding `factorPatt12` is true.

Note that `model.Matrix(*, sparse=TRUE)` from package **MatrixModels** may be often be preferable to `sparse.model.matrix()` nowadays, as `model.Matrix()` returns `modelMatrix` objects with additional slots `assign` and `contrasts` which relate back to the variables used.

`fac2sparse()`, the basic workhorse of `sparse.model.matrix()`, returns the *transpose* (`t`) of the model matrix.

### Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

### See Also

`model.matrix` in standard R’s package **stats**.

`model.Matrix` which calls `sparse.model.matrix` or `model.matrix` depending on its `sparse` argument may be preferred to `sparse.model.matrix`.

`as(f, "sparseMatrix")` (see `coerce(from = "factor", ...)` in the class doc `sparseMatrix`) produces the *transposed* sparse model matrix for a single factor `f` (and *no* contrasts).

### Examples

```
dd <- data.frame(a = gl(3,4), b = gl(4,1,12)) # balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd) # no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))

## Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
  Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
  all(sparse.model.matrix(~ 0+ a + b, dd) ==
  Matrix(model.matrix(~ 0+ a + b, dd), sparse=TRUE)))
```

```

(ff <- gl(3,4,, c("X","Y", "Z"))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgCMatrix"
##
## X 1 1 1 1 . . . . .
## Y . . . . 1 1 1 1 . . . .
## Z . . . . . . . 1 1 1 1

## can also be computed via sparse.model.matrix():
f30 <- gl(3,0 )
f12 <- gl(3,0, 12)
stopifnot(
  all.equal(t( fac2sparse(ff) ),
    sparse.model.matrix(~ 0+ff),
    tolerance = 0, check.attributes=FALSE),
  is(M <- fac2sparse(f30, drop= TRUE), "CsparseMatrix"), dim(M) == c(0, 0),
  is(M <- fac2sparse(f30, drop=FALSE), "CsparseMatrix"), dim(M) == c(3, 0),
  is(M <- fac2sparse(f12, drop= TRUE), "CsparseMatrix"), dim(M) == c(0,12),
  is(M <- fac2sparse(f12, drop=FALSE), "CsparseMatrix"), dim(M) == c(3,12)
)

```

sparseLU-class

*Sparse LU decomposition of a square sparse matrix*

## Description

Objects of this class contain the components of the LU decomposition of a sparse square matrix.

## Objects from the Class

Objects can be created by calls of the form `new("sparseLU", ...)` but are more commonly created by function `lu()` applied to a sparse matrix, such as a matrix of class `dgCMatrix`.

## Slots

**L:** Object of class `"dtCMatrix"`, the lower triangular factor from the left.  
**U:** Object of class `"dtCMatrix"`, the upper triangular factor from the right.  
**p:** Object of class `"integer"`, permutation applied from the left.  
**q:** Object of class `"integer"`, permutation applied from the right.  
**Dim:** the dimension of the original matrix; inherited from class `MatrixFactorization`.

## Extends

Class `"LU"`, directly. Class `"MatrixFactorization"`, by class `"LU"`.

## Methods

**expand** `signature(x = "sparseLU")` Returns a list with components `P`, `L`, `U`, and `Q`, where `P` and `Q` represent fill-reducing permutations, and `L`, and `U` the lower and upper triangular matrices of the decomposition. The original matrix corresponds to the product  $P'LUQ$ .

**Note**

The decomposition is of the form

$$A = P'LUQ,$$

or equivalently  $PAQ' = LU$ , where all matrices are sparse and of size  $n \times n$ . The matrices  $P$  and  $Q$ , and their transposes  $P'$  and  $Q'$  are permutation matrices,  $L$  is lower triangular and  $U$  is upper triangular.

**See Also**

**Examples**

```
## Extending the one in examples(lu), calling the matrix A,
## and confirming the factorization identities :
A <- as(readMM(system.file("external/pores_1.mtx",
                           package = "Matrix")),
        "CsparseMatrix")
## with dimnames(.) - to see that they propagate to L, U :
dimnames(A) <- dnA <- list(paste0("r", seq_len(nrow(A))),
                           paste0("C", seq_len(ncol(A))))
str(luA <- lu(A)) # p is a 0-based permutation of the rows
                  # q is a 0-based permutation of the columns
xA <- expand(luA)
## which is simply doing
stopifnot(identical(xA$L, luA@L),
          identical(xA$U, luA@U),
          identical(xA$P, as(luA@p + 1L, "pMatrix")),
          identical(xA$Q, as(luA@q + 1L, "pMatrix")))

P.LUQ <- with(xA, t(P) %*% L %*% U %*% Q)
stopifnot(all.equal(A, P.LUQ, tolerance = 1e-12),
          identical(dimnames(P.LUQ), dnA))
## permute rows and columns of original matrix
pA <- A[luA@p + 1L, luA@q + 1L]
stopifnot(identical(pA, with(xA, P %*% A %*% t(Q))))

pLU <- drop0(luA@L %*% luA@U) # L %*% U -- dropping extra zeros
stopifnot(all.equal(pA, pLU, tolerance = 1e-12))
```

---

SparseM-conversions

*Sparse Matrix Coercion from and to those from package **SparseM***

---

**Description**

Methods for coercion from and to sparse matrices from package **SparseM** are provided here, for ease of porting functionality to the **Matrix** package, and comparing functionality of the two packages. All these work via the usual `as(., "<class>")` coercion,

```
as(from, Class)
```

## Methods

```

from = "matrix.csr", to = "dgRMatrix" ...
from = "matrix.csc", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgTMatrix" ...
from = "dgRMatrix", to = "matrix.csr" ...
from = "dgCMatrix", to = "matrix.csc" ...
from = "dgTMatrix", to = "matrix.coo" ...

sparseMatrix

*General Sparse Matrix Construction from Nonzero Entries*

---

## Description

User friendly construction of a compressed, column-oriented, sparse matrix, inheriting from `class CsparseMatrix` (or `TsparseMatrix` if `giveCsparse` is false), from locations (and values) of its non-zero entries.

This is the recommended user interface rather than direct `new("***Matrix", ...)` calls.

## Usage

```

sparseMatrix(i = ep, j = ep, p, x, dims, dimnames,
             symmetric = FALSE, index1 = TRUE,
             giveCsparse = TRUE, check = TRUE, use.last.ij = FALSE)

```

## Arguments

<code>i, j</code>	integer vectors of the same length specifying the locations (row and column indices) of the non-zero (or non-TRUE) entries of the matrix. Note that for <i>repeated</i> pairs $(i_k, j_k)$ , when <code>x</code> is not missing, the corresponding $x_k$ are <i>added</i> , in consistency with the definition of the " <code>TsparseMatrix</code> " class, unless <code>use.last.ij</code> is true, in which case only the <i>last</i> of the corresponding $(i_k, j_k, x_k)$ triplet is used.
<code>p</code>	numeric (integer valued) vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of <code>i</code> , <code>j</code> or <code>p</code> must be missing.

<code>x</code>	optional values of the matrix entries. If specified, must be of the same length as <code>i</code> / <code>j</code> , or of length one where it will be recycled to full length. If missing, the resulting matrix will be a 0/1 pattern matrix, i.e., extending class <code>nsparseMatrix</code> .
<code>dims</code>	optional, non-negative, integer, dimensions vector of length 2. Defaults to <code>c(max(i), max(j))</code> .
<code>dimnames</code>	optional list of <code>dimnames</code> ; if not specified, none, i.e., <code>NULL</code> ones, are used.
<code>symmetric</code>	logical indicating if the resulting matrix should be symmetric. In that case, only the lower or upper triangle needs to be specified via $(i/j/p)$ .
<code>index1</code>	logical scalar. If <code>TRUE</code> , the default, the index vectors <code>i</code> and/or <code>j</code> are 1-based, as is the convention in R. That is, counting of rows and columns starts at 1. If <code>FALSE</code> the index vectors are 0-based so counting of rows and columns starts at 0; this corresponds to the internal representation.
<code>giveCsparse</code>	logical indicating if the result should be a <code>CsparseMatrix</code> or a <code>TsparseMatrix</code> . The default, <code>TRUE</code> is very often more efficient subsequently, but not always.
<code>check</code>	logical indicating if a validity check is performed; do not set to <code>FALSE</code> unless you know what you're doing!
<code>use.last.ij</code>	logical indicating if in the case of repeated, i.e., duplicated pairs $(i_k, j_k)$ only the last one should be used. The default, <code>FALSE</code> , corresponds to the " <code>TsparseMatrix</code> " definition.

## Details

Exactly one of the arguments `i`, `j` and `p` must be missing.

In typical usage, `p` is missing, `i` and `j` are vectors of positive integers and `x` is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If `i` or `j` is missing then `p` must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of `p`, `rep(seq_along(dp), dp)` where `dp <- diff(p)`, is used as the (1-based) row or column indices.

The values of `i`, `j`, `p` and `index1` are used to create 1-based index vectors `i` and `j` from which a `TsparseMatrix` is constructed, with numerical values given by `x`, if non-missing. Note that in that case, when some pairs  $(i_k, j_k)$  are repeated (aka “duplicated”), the corresponding  $x_k$  are *added*, in consistency with the definition of the "`TsparseMatrix`" class, unless `use.last.ij` is set to `true`.

By default, when `giveCsparse` is true, the `CsparseMatrix` derived from this triplet form is returned.

The reason for returning a `CsparseMatrix` object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in `x` then a `CsparseMatrix` is a unique representation of the sparse matrix.

## Value

A sparse matrix, by default (see `giveCsparse`) in compressed, column-oriented form, as an R object inheriting from both `CsparseMatrix` and `generalMatrix`.

**Note**

You *do* need to use `index1 = FALSE` (or add + 1 to `i` and `j`) if you want use the 0-based `i` (and `j`) slots from existing sparse matrices.

**See Also**

`Matrix(*, sparse=TRUE)` for the constructor of such matrices from a *dense* matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like `sparseMatrix()` is needed. Further `bdiag` and `Diagonal` for (block-)diagonal and `bandSparse` for banded sparse matrix constructors.

The standard R `xtabs(*, sparse=TRUE)`, for sparse tables and `sparse.model.matrix()` for building sparse model matrices.

Consider `CsparseMatrix` and similar class definition help files.

**Examples**

```
## simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x))
summary(A)
str(A) # note that *internally* 0-based row indices are used

## dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)

## i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))

## The slots are 0-index based, so
try( sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)) )
## fails and you should say so: 1-indexing is FALSE:
  sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

## the (i,j) pairs can be repeated, in which case the x's are summed
(args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, args))
## explicitly ask for elimination of such duplicates, so
## that the last one is used:
(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))
stopifnot(Aa[1,2] == 9, # 2+7 == 9
          A.[1,2] == 2) # 2 was *after* 7

## for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")]))

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
m
str(m)
stopifnot(identical(dimnames(m), dn))
```

```

sparseMatrix(x = 2.72, i=1:3, j=2:4) # recycling x
sparseMatrix(x = TRUE, i=1:3, j=2:4) # recycling x, |--> "lgCMatrix"

## no 'x' --> pattern* matrix:
(n <- sparseMatrix(i=1:6, j=rev(2:7)))# -> ngCMatrix

## an empty sparse matrix:
(e <- sparseMatrix(dims = c(4,6), i={}, j={}))

## a symmetric one:
(sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5,
  dims = c(7,7), symmetric=TRUE))
stopifnot(isSymmetric(sy),
  identical(sy, ## switch i <-> j {and transpose }
    t( sparseMatrix(j= c(2,4,3:5), i= c(4,7:5,5), x = 1:5,
      dims = c(7,7), symmetric=TRUE))))

## rsparsematrix() calls sparseMatrix() :
M1 <- rsparsematrix(1000, 20, nnz = 200)
summary(M1)

## pointers example in converting from other sparse matrix representations.
if(require(SparseM) && packageVersion("SparseM") >= 0.87 &&
  nzchar(dfil <- system.file("extdata", "rua_32_ax.rua", package = "SparseM"))) {
  X <- model.matrix(read.matrix.hb(dfil))
  XX <- sparseMatrix(j = X@ja, p = X@ia - 1L, x = X@ra, dims = X@dimension)
  validObject(XX)

  ## Alternatively, and even more user friendly :
  X. <- as(X, "Matrix") # or also
  X2 <- as(X, "sparseMatrix")
  stopifnot(identical(XX, X.), identical(X., X2))
}

```

---

sparseMatrix-class *Virtual Class "sparseMatrix" — Mother of Sparse Matrices*

---

## Description

Virtual Mother Class of All Sparse Matrices

## Slots

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class `Matrix`, see [Matrix](#).

## Extends

Class "Matrix", directly.

## Methods

**show** (object = "sparseMatrix"): The `show` method for sparse matrices prints “*structural*” zeroes as “.” using `printSpMatrix()` which allows further customization.

**print** signature(x = "sparseMatrix"),...

The `print` method for sparse matrices by default is the same as `show()` but can be called with extra optional arguments, see `printSpMatrix()`.

**format** signature(x = "sparseMatrix"),...

The `format` method for sparse matrices, see `formatSpMatrix()` for details such as the extra optional arguments.

**summary** (object = "sparseMatrix"): Returns an object of S3 class "sparseSummary" which is basically a `data.frame` with columns (i, j, x) (or just (i, j) for `nsparseMatrix` class objects) with the stored (typically non-zero) entries. The `print` method resembles Matlab’s way of printing sparse matrices, and also the MatrixMarket format, see `writeMM`.

**cbind2** (x = \*, y = \*): several methods for binding matrices together, column-wise, see the basic `cbind` and `rbind` functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

**rbind2** (x = \*, y = \*): binding matrices together row-wise, see `cbind2` above.

**determinant** (x = "sparseMatrix", logarithm=TRUE): `determinant()` methods for sparse matrices typically work via `Cholesky` or `lu` decompositions.

**diag** (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

**dim<-** signature(x = "sparseMatrix", value = "ANY"): allows to *reshape* a sparse matrix to a sparse matrix with the same entries but different dimensions. `value` must be of length two and fulfill `prod(value) == prod(dim(x))`.

**coerce** signature(from = "factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator **rows** stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values (NA) from the factor are translated to columns of all 0s.

See also `colSums`, `norm`, ... for methods with separate help pages.

## Note

In method selection for multiplication operations (i.e. `%*%` and the two-argument form of `crossprod`) the `sparseMatrix` class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a `dgeMatrix` and the appropriate sparse matrix method is used.

## See Also

`sparseMatrix`, and its references, such as `xtabs(*, sparse=TRUE)`, or `sparse.model.matrix()`, for constructing sparse matrices.

`T2graph` for conversion of "graph" objects (package **graph**) to and from sparse matrices.

## Examples

```
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
```

```

M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows

data(CAex); dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

## factor -> t( <sparse design matrix> ) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

## missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[, -i.mis] == X.[, -i.mis]))

```

sparseQR-class

*Sparse QR decomposition of a sparse matrix*

## Description

Objects class "sparseQR" represent a QR decomposition of a sparse  $n \times p$  rectangular matrix  $X$ , typically resulting from `qr()`

## Details

The decomposition is of the form  $A[p+1,] == Q \%*\% R$ , if the `q` slot is of length 0 or  $A[p+1, q+1] == Q \%*\% R$  where  $A$  is a sparse  $m \times n$  matrix ( $m \geq n$ ),  $R$  is an  $m \times n$  matrix that is zero below the main diagonal. The `p` slot is a 0-based permutation of  $1:m$  applied to the rows of the original matrix. If the `q` slot has length  $n$  it is a 0-based permutation of  $1:n$  applied to the columns of the original matrix to reduce the amount of "fill-in" in the matrix  $R$ .

The matrix  $Q$  is a "virtual matrix". It is the product of  $n$  Householder transformations. The information to generate these Householder transformations is stored in the `V` and `beta` slots.

The "sparseQR" methods for the `qr.*` functions return objects of class "dgeMatrix" (see `dgeMatrix`). Results from `qr.coef`, `qr.resid` and `qr.fitted` (when `k == ncol(R)`) are well-defined and should match those from the corresponding dense matrix calculations. However, because the matrix  $Q$  is not uniquely defined, the results of `qr.qy` and `qr.qty` do not necessarily match those from the corresponding dense matrix calculations.

Also, the results of `qr.qy` and `qr.qty` apply to the permuted column order when the `q` slot has length  $n$ .

## Objects from the Class

Objects can be created by calls of the form `new("sparseQR", ...)` but are more commonly created by function `qr` applied to a sparse matrix such as a matrix of class `dgCMatrix`.

### Slots

- V:** Object of class "dgCMatrix". The columns of *V* are the vectors that generate the Householder transformations of which the matrix *Q* is composed.
- beta:** Object of class "numeric", the normalizing factors for the Householder transformations.
- p:** Object of class "integer": Permutation (of 0:(n-1)) applied to the rows of the original matrix.
- R:** Object of class "dgCMatrix": An upper triangular matrix of dimension  $\backslash$
- q:** Object of class "integer": Permutation applied from the right. Can be of length 0 which implies no permutation.

### Methods

- qr.R** signature(qr = "sparseQR"): compute the upper triangular *R* matrix of the QR decomposition. Note that this currently warns because of possible permutation mismatch with the classical `qr.R()` result, *and* you can suppress these warnings by setting `options()` either "Matrix.quiet.qr.R" or (the more general) either "Matrix.quiet" to **TRUE**.
- qr.Q** signature(qr = "sparseQR"): compute the orthogonal *Q* matrix of the QR decomposition.
- qr.coef** signature(qr = "sparseQR", y = "ddenseMatrix"):...
- qr.coef** signature(qr = "sparseQR", y = "matrix"):...
- qr.coef** signature(qr = "sparseQR", y = "numeric"):...
- qr.fitted** signature(qr = "sparseQR", y = "ddenseMatrix"):...
- qr.fitted** signature(qr = "sparseQR", y = "matrix"):...
- qr.fitted** signature(qr = "sparseQR", y = "numeric"):...
- qr.qty** signature(qr = "sparseQR", y = "ddenseMatrix"):...
- qr.qty** signature(qr = "sparseQR", y = "matrix"):...
- qr.qty** signature(qr = "sparseQR", y = "numeric"):...
- qr.qy** signature(qr = "sparseQR", y = "ddenseMatrix"):...
- qr.qy** signature(qr = "sparseQR", y = "matrix"):...
- qr.qy** signature(qr = "sparseQR", y = "numeric"):...
- qr.resid** signature(qr = "sparseQR", y = "ddenseMatrix"):...
- qr.resid** signature(qr = "sparseQR", y = "matrix"):...
- qr.resid** signature(qr = "sparseQR", y = "numeric"):...
- solve** signature(a = "sparseQR", b = "ANY"): For `solve(a,b)`, simply uses `qr.coef(a,b)`.

### See Also

`qr`, `qr.Q`, `qr.R`, `qr.fitted`, `qr.resid`, `qr.coef`, `qr.qty`, `qr.qy`, `dgCMatrix`, `dgeMatrix`.

**Examples**

```

data(KNex)
mm <- KNex $ mm
y <- KNex $ y
y. <- as(as.matrix(y), "dgCMatrix")
str(qrm <- qr(mm))
qc <- qr.coef (qrm, y); qc. <- qr.coef (qrm, y.) # 2nd failed in Matrix <= 1.1-0
qf <- qr.fitted(qrm, y); qf. <- qr.fitted(qrm, y.)
qs <- qr.resid (qrm, y); qs. <- qr.resid (qrm, y.)
stopifnot(all.equal(qc, as.numeric(qc.), tolerance=1e-12),
          all.equal(qf, as.numeric(qf.), tolerance=1e-12),
          all.equal(qs, as.numeric(qs.), tolerance=1e-12),
          all.equal(qf+qs, y, tolerance=1e-12))

```

sparseVector

*Sparse Vector Construction from Nonzero Entries***Description**

User friendly construction sparse vectors, i.e., objects inheriting from `class sparseVector`, from indices and values of its non-zero entries.

**Usage**

```
sparseVector(x, i, length)
```

**Arguments**

<code>x</code>	vector of the non zero entries.
<code>i</code>	integer vector (of the same length as <code>x</code> ) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector.
<code>length</code>	length of the sparse vector.

**Details**

zero entries in `x` are dropped automatically, analogously as `drop0()` acts on sparse matrices.

**Value**

a sparse vector, i.e., inheriting from `class sparseVector`.

**Author(s)**

Martin Maechler

**See Also**

`sparseMatrix()` constructor for sparse matrices; the class `sparseVector`.

## Examples

```
str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss,
  sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
    i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))
```

---

sparseVector-class *Sparse Vector Classes*

---

## Description

**Sparse Vector Classes:** The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we've mainly implemented methods for the d\*, l\* and n\* ones.

## Slots

- length:** class "numeric" - the [length](#) of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", `.Machine$integer.max`, on purpose.
- i:** class "numeric" - the (1-based) indices of the non-zero entries. Must *not* be NA and strictly sorted increasingly.  
Note that "integer" is "part of" "numeric", and can (and often will) be used for non-huge sparseVectors.
- x:** (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.  
Note that "nsparseVector"s have no x slot. Further, mainly for ease of method definitions, we've defined the class union (see [setClassUnion](#)) of all sparse vector classes which *have* an x slot, as class "xsparseVector".

## Methods

- length** signature(x = "sparseVector"): simply extracts the length slot.
- show** signature(object = "sparseVector"): The [show](#) method for sparse vectors prints "structural" zeroes as "." using the non-exported `prSpVector` function which allows further customization such as replacing "." by " " (blank).  
Note that [options](#)(`max.print`) will influence how many entries of large sparse vectors are printed at all.
- as.vector** signature(x = "sparseVector", mode = "character") coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as `as(x, "vector")`.
- as ..**: see [coerce](#) below
- coerce** signature(from = "sparseVector", to = "sparseMatrix"), and
- coerce** signature(from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices ([sparseMatrix](#)) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.

**dim<-** signature(x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from [sparseMatrix](#), of the appropriate dimension.

**head** signature(x = "sparseVector"): as with R's (package [util](#)) [head](#), `head(x, n)` (for  $n \geq 1$ ) is equivalent to `x[1:n]`, but here can be much more efficient, see the example.

**tail** signature(x = "sparseVector"): analogous to [head](#), see above.

**toeplitz** signature(x = "sparseVector"): as [toeplitz\(x\)](#), produce the  $n \times n$  Toeplitz matrix from x, where  $n = \text{length}(x)$ .

**rep** signature(x = "sparseVector") repeat x, with the same argument list (x, times, length.out, each, ...) as the default method for `rep()`.

**Ops** signature(e1 = "sparseVector", e2 = "\*"): define arithmetic, compare and logic operations, (see [Ops](#)).

**Summary** signature(x = "sparseVector"): define all the [Summary](#) methods.

[ signature(x = "atomicVector", i = ...): not only can you subset (aka "*index into*") sparseVectors `x[i]` using sparseVectors `i`, but we also support efficient subsetting of traditional vectors `x` by logical sparse vectors (i.e., `i` of class "nsparseVector" or "lsparseVector").

**is.na, is.finite, is.infinite** (x = "sparseVector"), and

**is.na, is.finite, is.infinite** (x = "nsparseVector"): return [logical](#) or "nsparseVector" of the same length as x, indicating if/where x is [NA](#) (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

## See Also

[sparseVector\(\)](#) for friendly construction of sparse vectors (apart from `as(*, "sparseVector")`).

## Examples

```
getClass("sparseVector")
getClass("dsparseVector")
getClass("xsparseVector") # those with an 'x' slot

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
(ss <- as(sx, "sparseVector"))

ix <- as.integer(round(sx))
(is <- as(ix, "sparseVector"))
## an "isparseVector" (!)

## rep() works too:
(ri <- rep(is, length.out= 25))

## Using `dim<-` as in base R :
r <- ss
dim(r) <- c(4,5) # becomes a sparse Matrix:
r
## or coercion (as as.matrix() in base R):
as(ss, "Matrix")
stopifnot(all(ss == print(as(ss, "CsparseMatrix"))))

## currently has "non-structural" FALSE -- printing as ":"
```

```

(lis <- is & FALSE)
(nn <- is[is == 0]) # all "structural" FALSE

## NA-case
sN <- sx; sN[4] <- NA
(svN <- as(sN, "sparseVector"))

v <- as(c(0,0,3, 3.2, rep(0,9),-3,0,-1, rep(0,20),5,0),
        "sparseVector")
v <- rep(rep(v, 50), 5000)
set.seed(1); v[sample(v@i, 1e6)] <- 0
str(v)

system.time(for(i in 1:4) hv <- head(v, 1e6))
##   user   system elapsed
## 0.033    0.000    0.032
system.time(for(i in 1:4) h2 <- v[1:1e6])
##   user   system elapsed
## 1.317    0.000    1.319

stopifnot(identical(hv, h2),
           identical(is | FALSE, is != 0),
           validObject(svN), validObject(lis), as.logical(is.na(svN[4])),
           identical(is^2 > 0, is & TRUE),
           all(!lis), !any(lis), length(nn@i) == 0, !any(nn), all(!nn),
           sum(lis) == 0, !prod(lis), range(lis) == c(0,0))

## create and use the t(.) method:
t(x20 <- sparseVector(c(9,3:1), i=c(1:2,4,7), length=20))
(T20 <- toeplitz(x20))
stopifnot(is(T20, "symmetricMatrix"), is(T20, "sparseMatrix"),
           identical(unname(as.matrix(T20)),
                     toeplitz(as.vector(x20))))

```

---

spMatrix

---

*Sparse Matrix Constructor From Triplet*

---

## Description

User friendly construction of a sparse matrix (inheriting from class [TsparseMatrix](#)) from the triplet representation.

## Usage

```
spMatrix(nrow, ncol, i = integer(), j = integer(), x = numeric())
```

## Arguments

nrow, ncol	integers specifying the desired number of rows and columns.
i, j	integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix.

$x$  atomic vector of the same length as  $i$  and  $j$ , specifying the values of the non-zero entries.

### Value

A sparse matrix in triplet form, as an R object inheriting from both `TsparseMatrix` and `generalMatrix`.

The matrix  $M$  will have  $M[i[k], j[k]] == x[k]$ , for  $k = 1, 2, \dots, n$ , where  $n = \text{length}(i)$  and  $M[i', j'] == 0$  for all other pairs  $(i', j')$ .

### See Also

`Matrix(*, sparse=TRUE)` for the more usual constructor of such matrices; similarly, `sparseMatrix` which is a bit more general than `spMatrix()` and returns a `CsparseMatrix` which is often slightly more desirable. Further, `bdiag` and `Diagonal` for (block-)diagonal matrix constructors.

Consider `TsparseMatrix` and similar class definition help files.

### Examples

```
## simple example
A <- spMatrix(10,20, i = c(1,3:8),
                j = c(2,9,6:10),
                x = 7 * (1:7))

A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9, 30, i = rep(1:9, 3), 1:27,
              (1:27) %% 4 != 1)
L # an "lgTMatrix"

### This is a useful utility, to be used for experiments :

rSpMatrix <- function(nrow, ncol, nnz,
                      rand.x = function(n) round(rnorm(nnz), 2))
{
  ## Purpose: random sparse matrix
  ## -----
  ## Arguments: (nrow,ncol): dimension
  ##             nnz      : number of non-zero entries
  ##             rand.x:  random number generator for 'x' slot
  ## -----
  ## Author: Martin Maechler, Date: 14.-16. May 2007
  stopifnot((nnz <- as.integer(nnz)) >= 0,
            nrow >= 0, ncol >= 0,
            nnz <= nrow * ncol)
  spMatrix(nrow, ncol,
           i = sample(nrow, nnz, replace = TRUE),
           j = sample(ncol, nnz, replace = TRUE),
           x = rand.x(nnz))
}

M1 <- rSpMatrix(100000, 20, nnz = 200)
summary(M1)
```

---

symmetricMatrix-class

*Virtual Class of Symmetric Matrices in Package Matrix*

---

## Description

The virtual class of symmetric matrices, "symmetricMatrix", from the package **Matrix** contains numeric and logical, dense and sparse matrices, e.g., see the examples.

The main use is in methods (and C functions) that can deal with all symmetric matrices.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there. See below, about storing only one of the two Dimnames components.

**factors:** a list of matrix factorizations, also from the `Matrix` class.

## Extends

Class "Matrix", directly.

## Methods

**coerce** signature(from = "ddiMatrix", to = "symmetricMatrix"): and many other coercion methods, some of which are particularly optimized.

**dimnames** signature(object = "symmetricMatrix"): returns *symmetric dimnames*, even when the Dimnames slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

**isSymmetric** signature(object = "symmetricMatrix"): returns TRUE trivially.

There's a C function `symmetricMatrix_validate()` called by the internal validity checking functions, and also from [getValidity](#)(`getClass("symmetricMatrix")`).

## Validity and dimnames

The validity checks do not require a symmetric Dimnames slot, so it can be `list(NULL, <character>)`, e.g., for efficiency. However, [dimnames\(\)](#) and other functions and methods should behave as if the dimnames were symmetric, i.e., with both list components identical.

## See Also

[isSymmetric](#) which has efficient methods ([isSymmetric-methods](#)) for the **Matrix** classes. Classes [triangularMatrix](#), and, e.g., [dsyMatrix](#) for numeric *dense* matrices, or [lsCMatrix](#) for a logical *sparse* matrix class.

## Examples

```
## An example about the symmetric Dimnames:
sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5, dims = c(7,7),
                  symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
sy@Dimnames # internally only one part is stored
dimnames(sy) # both parts - as sy *is* symmetrical

showClass("symmetricMatrix")

## The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

## Methods -- applicable to all subclasses above:
showMethods(classes = "symmetricMatrix")
```

---

symmpart

*Symmetric Part and Skew(symmetric) Part of a Matrix*

---

## Description

`symmpart(x)` computes the symmetric part  $(x + t(x))/2$  and `skewpart(x)` the skew symmetric part  $(x - t(x))/2$  of a square matrix `x`, more efficiently for specific Matrix classes.

Note that `x == symmpart(x) + skewpart(x)` for all square matrices – apart from extra-neous NA values in the RHS.

## Usage

```
symmpart(x)
skewpart(x)
```

## Arguments

`x` a *square* matrix; either “traditional” of class “matrix”, or typically, inheriting from the `Matrix` class.

## Details

These are generic functions with several methods for different matrix classes, use e.g., `showMethods(symmpart)` to see them.

If the row and column names differ, the result will use the column names unless they are (partly) NULL where the row names are non-NULL (see also the examples).

## Value

`symmpart()` returns a symmetric matrix, inheriting from `symmetricMatrix` iff `x` inherited from `Matrix`.

`skewpart()` returns a skew-symmetric matrix, typically of the same class as `x` (or the closest “general” one, see `generalMatrix`).

**See Also**

[isSymmetric.](#)

**Examples**

```
m <- Matrix(1:4, 2,2)
symmpart(m)
skewpart(m)

stopifnot(all(m == symmpart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))
stopifnot(all(m == symmpart(m) + skewpart(m)))
colnames(m) <- NULL
stopifnot(all(m == symmpart(m) + skewpart(m)))
dimnames(m) <- unname(dn)
stopifnot(all(m == symmpart(m) + skewpart(m)))

## investigate the current methods:
showMethods(skewpart, include = TRUE)
```

---

triangularMatrix-class

*Virtual Class of Triangular Matrices in Package Matrix*

---

**Description**

The virtual class of triangular matrices, "triangularMatrix", the package **Matrix** contains *square* (`nrow == ncol`) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

**Slots**

**uplo:** String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when `diag` is "U". For [denseMatrix](#) classes, they need to be allocated though, i.e., the length of the `x` slot does not depend on `diag`.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

**Extends**

Class "Matrix", directly.

## Methods

There's a C function `triangularMatrix_validity()` called by the internal validity checking functions.

Currently, `Schur`, `isSymmetric` and `as()` (i.e. `coerce`) have methods with `triangularMatrix` in their signature.

## See Also

`isTriangular()` for testing any matrix for triangularity; classes `symmetricMatrix`, and, e.g., `dtrMatrix` for numeric *dense* matrices, or `ltCMatrix` for a logical *sparse* matrix subclass of "triangularMatrix".

## Examples

```
showClass("triangularMatrix")

## The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")
```

---

TsparseMatrix-class

*Class "TsparseMatrix" of Sparse Matrices in Triplet Form*

---

## Description

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See `showClass("TsparseMatrix")` for its subclasses.

## Slots

- Dim, Dimnames: from the "Matrix" class,
- i: Object of class "integer" - the row indices of non-zero entries *in 0-base*, i.e., must be in `0:(nrow(.)-1)`.
- j: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot `i` and *0-based* as well, i.e., in `0:(ncol(.)-1)`. For numeric Tsparse matrices, `(i, j)` pairs can occur more than once, see `dgTMatrix`.

## Extends

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

Extraction ("`[`"") methods, see `[]-methods`.

**Note**

Most operations with sparse matrices are performed using the compressed, column-oriented or `CsparseMatrix` representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a `CsparseMatrix` for further operations.

Note that all `new()`, `spMatrix` and `sparseMatrix(*, giveCsparse=FALSE)` constructors for "TsparseMatrix" classes implicitly add  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs, see, the example below, or also "dgTMatrix".

For convenience, methods for some operations such as `%%` and `crossprod` are defined for `TsparseMatrix` objects. These methods simply coerce the `TsparseMatrix` object to a `CsparseMatrix` object then perform the operation.

**See Also**

its superclass, `sparseMatrix`, and the `dgTMatrix` class, for the links to other classes.

**Examples**

```
showClass("TsparseMatrix")
## or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)

T3 <- spMatrix(3,4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !
```

---

uniqTsparse

*Unique TsparseMatrix Representations*

---

**Description**

Detect or “unify” non-unique `TsparseMatrix` matrices.

Note that `new()`, `spMatrix` or `sparseMatrix` constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs.

`anyDuplicatedT()` reports the index of the first duplicated pair, or 0 if there is none.

`uniqTsparseT(x)` replaces duplicated index pairs  $(i, j)$  and their corresponding  $x$  slot entries by the triple  $(i, j, sx)$  where  $sx = \text{sum}(x \text{ [all pairs matching } (i, j) >])$ , and for logical  $x$ , addition is replaced by logical *or*.

**Usage**

```
uniqTsparse(x, class.x = c(class(x)))
anyDuplicatedT(x, di = dim(x))
```

**Arguments**

<code>x</code>	a sparse matrix stored in triplet form, i.e., inheriting from class <code>TsparseMatrix</code> .
<code>class.x</code>	optional character string specifying <code>class(x)</code> .
<code>di</code>	the matrix dimension of <code>x</code> , <code>dim(x)</code> .

**Value**

`uniqTsparse(x)` returns a `TsparseMatrix` “like `x`”, of the same class and with the same elements, just internally possibly changed to “unique”  $(i, j, x)$  triplets in *sorted* order.

`anyDuplicatedT(x)` returns an `integer` as `anyDuplicated`, the *index* of the first duplicated entry (from the  $(i, j)$  pairs) if there is one, and 0 otherwise.

**See Also**

`TsparseMatrix`, for uniqueness, notably `dgTMatrix`.

**Examples**

```
example("dgTMatrix-class", echo=FALSE)
## -> 'T2' with (i,j,x) slots of length 5 each
T2u <- uniqTsparse(T2)
stopifnot(## They "are" the same (and print the same):
  all.equal(T2, T2u, tol=0),
  ## but not internally:
  anyDuplicatedT(T2) == 2,
  anyDuplicatedT(T2u) == 0,
  length(T2@x) == 5,
  length(T2u@x) == 3)

## is 'x' a "uniq Tsparse" Matrix ? [requires x to be TsparseMatrix!]
non_uniqT <- function(x, di = dim(x))
  is.unsorted(x@j) || anyDuplicatedT(x, di)
non_uniqT(T2) # TRUE
non_uniqT(T2u) # FALSE

## Logical l.TMatrix and n.TMatrix :
(L2 <- T2 > 0)
validObject(L2u <- uniqTsparse(L2))
(N2 <- as(L2, "nMatrix"))
validObject(N2u <- uniqTsparse(N2))
stopifnot(N2u@i == L2u@i, L2u@i == T2u@i, N2@i == L2@i, L2@i == T2@i,
  N2u@j == L2u@j, L2u@j == T2u@j, N2@j == L2@j, L2@j == T2@j)
# now with a nasty NA [partly failed in Matrix 1.1-5]:
L2.N <- L2; L2.N@x[2] <- NA; L2.N
validObject(L2.N)
(m2N <- as.matrix(L2.N)) # looks "ok"
iL <- as.integer(m2N)
stopifnot(identical(10L, which(is.na(match(iL, 0:1)))))
symnum(m2N)
```

**Description**

“Packed” matrix storage here applies to dense matrices (`denseMatrix`) only, and there is available only for symmetric (`symmetricMatrix`) or triangular (`triangularMatrix`) matrices, where only one triangle of the matrix needs to be stored.

`unpack()` unpacks “packed” matrices, where  
`pack()` produces “packed” matrices.

**Usage**

```
pack(x, ...)
## S4 method for signature 'matrix'
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)
```

**Arguments**

<code>x</code>	<b>for</b> <code>unpack()</code> : a matrix stored in packed form, e.g., of class <code>"d?pMatrix"</code> where "?" is "t" for triangular or "s" for symmetric. <b>for</b> <code>pack()</code> : a (symmetric or triangular) matrix stored in full storage.
<code>symmetric</code>	logical (including NA) for optionally specifying if <code>x</code> is symmetric (or rather triangular).
<code>upperTri</code>	(for the triangular case only) logical (incl. NA) indicating if <code>x</code> is upper (or lower) triangular.
<code>...</code>	further arguments passed to or from other methods.

**Details**

These are generic functions with special methods for different types of packed (or non-packed) symmetric or triangular dense matrices. Use `showMethods("unpack")` to list the methods for `unpack()`, and similarly for `pack()`.

**Value**

**for** `unpack()`: A `Matrix` object containing the full-storage representation of `x`.

**for** `pack()`: A packed `Matrix` (i.e. of class `"..pMatrix"`) representation of `x`.

**Examples**

```
showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- as(cp4,"dtpMatrix")# [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
  dim(s) == dim(sp), all(s == sp),
  dim(mt) == dim(pt), all(mt == pt), all(mt == tt))
showMethods("pack")
```

Unused-classes

*Virtual Classes Not Yet Really Implemented and Used***Description**

`iMatrix` is the virtual class of all integer (S4) matrices. It extends the `Matrix` class directly.

`zMatrix` is the virtual class of all `complex` (S4) matrices. It extends the `Matrix` class directly.

**Examples**

```
showClass("iMatrix")
showClass("zMatrix")
```

updown

*Up- and Down-Dating a Cholesky Decomposition***Description**

Compute the up- or down-dated Cholesky decomposition

**Usage**

```
updown(update, C, L)
```

**Arguments**

<code>update</code>	logical (TRUE or FALSE) or "+" or "-" indicating if an up- or a down-date is to be computed.
<code>C</code>	any R object, coercable to a sparse matrix (i.e., of subclass of <code>sparseMatrix</code> ).
<code>L</code>	a Cholesky factor, specifically, of class " <code>CHMfactor</code> ".

**Value**

an updated Cholesky factor, of the same dimension as `L`. Typically of class "`dCHMimpl`" (a subclass of "`CHMfactor`").

**Methods**

```
signature(update = "character", C = "mMatrix", L = "CHMfactor") ..
signature(update = "logical", C = "mMatrix", L = "CHMfactor") ..
```

**Author(s)**

**Examples**

```
dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p= c(0:2, 4,4,6), x = 1:6, dimnames = dn)
cA <- Cholesky(A <- crossprod(m) + Diagonal(5))
166 * as(cA,"Matrix") ^ 2
uc1 <- updown("+", Diagonal(5), cA)
## Hmm: this loses positive definiteness:
uc2 <- updown("-", 2*Diagonal(5), cA)
image(show(as(cA, "Matrix"))
image(show(c2 <- as(uc2,"Matrix")))# severely negative entries
##--> Warning
```

---

USCounties

*USCounties Contiguity Matrix*

---

**Description**

This matrix represents the contiguities of 3111 US counties using the Queen criterion of at least a single shared boundary point. The representation is as a row standardised spatial weights matrix transformed to a symmetric matrix (see Ord (1975), p. 125).

**Usage**

```
data(USCounties)
```

**Format**

A 3111<sup>2</sup> symmetric sparse matrix of class [dsCMatrix](#) with 9101 non-zero entries.

**Details**

The data were read into R using [read.gal](#), and row-standardised and transformed to symmetry using [nb2listw](#) and [similar.listw](#). This spatial weights object was converted to class [dsCMatrix](#) using [as\\_dsTMatrix\\_listw](#) and coercion.

**Source**

The data were retrieved from <http://sal.uiuc.edu/weights/zips/usc.zip>, files “usc.txt” and “usc\\_q.GAL”, with permission for use and distribution from Luc Anselin.

**References**

Ord, J. K. (1975) Estimation methods for models of spatial interaction; *Journal of the American Statistical Association* **70**, 120–126.

**Examples**

```

data(USCounties)
(n <- ncol(USCounties))
IM <- .symDiagonal(n)
nn <- 50
set.seed(1)
rho <- runif(nn, 0, 1)
system.time(MJ <- sapply(rho, function(x)
  determinant(IM - x * USCounties, logarithm = TRUE)$modulus))

## can be done faster, by update()ing the Cholesky factor:
nWC <- -USCounties
C1 <- Cholesky(nWC, Imult = 2)
system.time(MJ1 <- n * log(rho) +
  sapply(rho, function(x)
    2 * c(determinant(update(C1, nWC, 1/x))$modulus)))
all.equal(MJ, MJ1)

C2 <- Cholesky(nWC, super = TRUE, Imult = 2)
system.time(MJ2 <- n * log(rho) +
  sapply(rho, function(x)
    2 * c(determinant(update(C2, nWC, 1/x))$modulus)))
all.equal(MJ, MJ2)
system.time(MJ3 <- n * log(rho) + Matrix::ldetL2up(C1, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ3))
system.time(MJ4 <- n * log(rho) + Matrix::ldetL2up(C2, nWC, 1/rho))
stopifnot(all.equal(MJ, MJ4))

```

[-methods

*Methods for "[": Extraction or Subsetting in Package 'Matrix'***Description**

Methods for "[", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

**Methods**

There are more than these:

```

x = "Matrix", i = "missing", j = "missing", drop = "ANY" ...
x = "Matrix", i = "numeric", j = "missing", drop = "missing" ...
x = "Matrix", i = "missing", j = "numeric", drop = "missing" ...
x = "dsparseMatrix", i = "missing", j = "numeric", drop = "logical" ...
x = "dsparseMatrix", i = "numeric", j = "missing", drop = "logical" ...
x = "dsparseMatrix", i = "numeric", j = "numeric", drop = "logical" ...

```

**See Also**

[\[<--methods](#) for subassignment to "Matrix" objects. [Extract](#) about the standard extraction.

## Examples

```
str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[]))
m[2, 3]    # simple number
m[2, 3:4]  # simple numeric of length 2
m[2, 3:4, drop=FALSE] # sub matrix of class 'dgeMatrix'
## rows or columns only:
m[1,]      # first row, as simple numeric vector
m[,1:2]    # sub matrix of first two columns

showMethods("[", inherited = FALSE)
```

---

[<-methods

Methods for "[<-" - Assigning to Subsets for 'Matrix'

---

## Description

Methods for "[<-", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

**Note:** Contrary to standard `matrix` assignment in base R, in `x[...] <- val` it is typically an **error** (see [stop](#)) when the [type](#) or [class](#) of `val` would require the class of `x` to be changed, e.g., when `x` is logical, say `"lsparseMatrix"`, and `val` is numeric. In other cases, e.g., when `x` is a `"nsparseMatrix"` and `val` is not `TRUE` or `FALSE`, a warning is signalled, and `val` is “interpreted” as [logical](#), and (logical) `NA` is interpreted as `TRUE`.

## Methods

There are *many many* more than these:

`x = "Matrix", i = "missing", j = "missing", value = "ANY"` is currently a simple fallback method implementation which ensures “readable” error messages.

`x = "Matrix", i = "ANY", j = "ANY", value = "ANY"` currently gives an error

`x = "denseMatrix", i = "index", j = "missing", value = "numeric" ...`

`x = "denseMatrix", i = "index", j = "index", value = "numeric" ...`

`x = "denseMatrix", i = "missing", j = "index", value = "numeric" ...`

## See Also

[\[-methods](#) for subsetting "Matrix" objects; the [index](#) class; [Extract](#) about the standard subset assignment (and extraction).

## Examples

```
set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <- replaces every entry
a
## as do these:
a[,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
```

```

m[3, 3:4] <- 3:4 # simple numeric of length 2

## sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

## rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6), ] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")

```

---

%&%-methods*Boolean Arithmetic Matrix Products: %&% and Methods*

---

## Description

For boolean or “pattern” matrices, i.e., R objects of class `nMatrix`, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package **Matrix**, we use the binary operator `%&%` (aka “infix”) function) for this and provide methods for all our matrices and the traditional R matrices (see `matrix`).

## Value

a pattern matrix, i.e., inheriting from `"nMatrix"`, or an `"ldiMatrix"` in case of a diagonal matrix.

## Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and `sparseVectors` in package **Matrix**.

```

signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "mMatrix", y = "mMatrix")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "mMatrix")
signature(x = "mMatrix", y = "sparseVector")
signature(x = "sparseVector", y = "sparseVector")

```

## Note

The current implementation ends up coercing both `x` and `y` to (virtual) class `nsparseMatrix` which may be quite inefficient. A future implementation may well return a matrix with **different** class, but the “same” content, i.e., the same matrix entries  $m_{ij}$ .

**Examples**

```

set.seed(7)
L <- Matrix(rnorm(20) > 1,      4,5)
(N <- as(L, "nMatrix"))
D <- Matrix(round(rnorm(30)), 5,6) # -> values in -1:1 (for this seed)
L %&% D
stopifnot(identical(L %&% D, N %&% D),
           all(L %&% D == as((L %*% abs(D)) > 0, "sparseMatrix")))

## cross products , possibly with boolArith = TRUE :
crossprod(N)      # -> sparse patter'n' (TRUE/FALSE : boolean arithmetic)
crossprod(N +0)   # -> numeric Matrix (with same "pattern")
stopifnot(all(crossprod(N) == t(N) %&% N),
           identical(crossprod(N), crossprod(N +0, boolArith=TRUE)),
           identical(crossprod(L), crossprod(N , boolArith=FALSE)))
crossprod(D, boolArith = TRUE) # pattern: "nsCMatrix"
crossprod(L, boolArith = TRUE) # ditto
crossprod(L, boolArith = FALSE) # numeric: "dsCMatrix"

```

## Chapter 18

# The boot package

---

`abc.ci`

*Nonparametric ABC Confidence Intervals*

---

### Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

### Usage

```
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95,
       eps=0.001/n, ...)
```

### Arguments

<code>data</code>	A data set expressed as a vector, matrix or data frame.
<code>statistic</code>	A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to <code>statistic</code> will be normalized to sum to 1 within each stratum. Any other arguments should be passed to <code>abc.ci</code> as part of the <code>...{}</code> argument.
<code>index</code>	If <code>statistic</code> returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.
<code>strata</code>	A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.
<code>conf</code>	A scalar or vector containing the confidence level(s) of the required interval(s).
<code>eps</code>	The value of epsilon to be used for the numerical differentiation.
<code>...</code>	Any other arguments for <code>statistic</code> . These will be passed unchanged to <code>statistic</code> each time it is called within <code>abc.ci</code> .

## Details

This function is based on the function `abcnon` written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is  $2 \times n + 2 + 2 \times \text{length}(\text{conf})$  where  $n$  is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

## Value

A `length(conf)` by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
abc.ci(grav1, mean.diff, strata = grav1$series)
```

---

acme

*Monthly Excess Returns*

---

## Description

The `acme` data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such as a U.S. Treasury bill.

**Usage**

```
acme
```

**Format**

This data frame contains the following columns:

`month` A character string representing the month of the observation.

`market` The excess return of the market as a whole.

`acme` The excess return for the Acme Cleveland Corporation.

**Source**

The data were obtained from

Simonoff, J.S. and Tsai, C.-L. (1994) Use of modified profile likelihood for improved tests of constancy of variance in regression. *Applied Statistics*, **43**, 353–370.

---

aids

*Delay in AIDS Reporting in England and Wales*

---

**Description**

The `aids` data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

**Usage**

```
aids
```

**Format**

This data frame contains the following columns:

`year` The year of the diagnosis.

`quarter` The quarter of the year in which diagnosis was made.

`delay` The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of `delay` is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).

`dud` An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

`time` The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

`y` The number of AIDS cases reported.

### Source

The data were obtained from

---

aircondit

*Failures of Air-conditioning Equipment*

---

### Description

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The `aircondit` data frame contains the intervals for the ninth aircraft while `aircondit7` contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

### Usage

`aircondit`

### Format

The data frames contain the following column:

`hours` The time interval in hours between successive failures of the air-conditioning equipment

### Source

The data were taken from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

---

amis*Car Speeding and Warning Signs*

---

**Description**

The `amis` data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

**Usage**

```
amis
```

**Format**

This data frame contains the following columns:

`speed` Speeds of cars (in miles per hour).

`period` A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.

`warning` A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.

`pair` A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

**Source**

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

aml

*Remission Times for Acute Myelogenous Leukaemia***Description**

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

**Usage**

```
aml
```

**Format**

This data frame contains the following columns:

`time` The length of the complete remission (in weeks).

`cens` An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.

`group` The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

**Note**

Package **survival** also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

**Source**

The data were obtained from

Miller, R.G. (1981) *Survival Analysis*. John Wiley.

**References**

---

`beaver`*Beaver Body Temperature Data*

---

## Description

The `beaver` data frame has 100 rows and 4 columns. It is a multivariate time series of class `"ts"` and also inherits from class `"data.frame"`.

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

## Usage

```
beaver
```

## Format

This data frame contains the following columns:

`day` The day number. The data includes only data from day 307 and early 308.

`time` The time of day formatted as hour-minute.

`temp` The body temperature in degrees Celsius.

`activ` The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

## Source

The data were obtained from

Reynolds, P.S. (1994) Time-series analyses of beaver body temperatures. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 211–228. John Wiley.

bigcity	<i>Population of U.S. Cities</i>
---------	----------------------------------

---

### Description

The `bigcity` data frame has 49 rows and 2 columns.

The `city` data frame has 10 rows and 2 columns.

The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The `city` data frame consists of the first 10 observations in `bigcity`.

### Usage

```
bigcity
```

### Format

This data frame contains the following columns:

- u The 1920 population.
- x The 1930 population.

### Source

The data were obtained from

Cochran, W.G. (1977) *Sampling Techniques*. Third edition. John Wiley

### References

boot	<i>Bootstrap Resampling</i>
------	-----------------------------

---

### Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to `boot`. Importance resampling weights may be specified.

### Usage

```
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
      strata = rep(1,n), L = NULL, m = 0, weights = NULL,
      ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ...,
      parallel = c("no", "multicore", "snow"),
      ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

<code>data</code>	The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.
<code>statistic</code>	A function which when applied to data returns a vector containing the statistic(s) of interest. When <code>sim = "parametric"</code> , the first argument to <code>statistic</code> must be the data. For each replicate a simulated dataset returned by <code>ran.gen</code> will be passed. In all other cases <code>statistic</code> must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to <code>statistic</code> through the <code>...</code> argument.
<code>R</code>	The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights.
<code>sim</code>	A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.
<code>stype</code>	A character string indicating what the second argument of <code>statistic</code> represents. Possible values of <code>stype</code> are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for <code>sim = "parametric"</code> .
<code>strata</code>	An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when <code>sim = "parametric"</code> . When <code>strata</code> is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.
<code>L</code>	Vector of influence values evaluated at the observations. This is used only when <code>sim</code> is "antithetic". If not supplied, they are calculated through a call to <code>empinf</code> . This will use the infinitesimal jackknife provided that <code>stype</code> is "w", otherwise the usual jackknife is used.
<code>m</code>	The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when <code>sim</code> is "ordinary". <code>m</code> will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of <code>statistic</code> , which should also take an argument giving the vector of indices of the errors to be used for the predictions.
<code>weights</code>	Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in <code>data</code> . When simulation from more than one set of weights is required, <code>weights</code> should be a matrix where each row of the matrix is one set of importance weights. If <code>weights</code> is a matrix then <code>R</code> must be a vector of length <code>nrow(weights)</code> . This parameter is ignored if <code>sim</code> is not "ordinary" or "balanced".

<code>ran.gen</code>	This function is used only when <code>sim = "parametric"</code> when it describes how random values are to be generated. It should be a function of two arguments. The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to <code>ran.gen</code> . The returned value should be a simulated data set of the same form as the observed data which will be passed to <code>statistic</code> to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If <code>ran.gen</code> is not specified, the default is a function which returns the original data in which case all simulation should be included as part of <code>statistic</code> . Use of <code>sim = "parametric"</code> with a suitable <code>ran.gen</code> allows the user to implement any types of nonparametric resampling which are not supported directly.
<code>mle</code>	The second argument to be passed to <code>ran.gen</code> . Typically these will be maximum likelihood estimates of the parameters. For efficiency <code>mle</code> is often a list containing all of the objects needed by <code>ran.gen</code> which can be calculated using the original data set only.
<code>simple</code>	logical, only allowed to be <code>TRUE</code> for <code>sim = "ordinary"</code> , <code>stype = "i"</code> , <code>n = 0</code> (otherwise ignored with a warning). By default a <code>n</code> by <code>R</code> index array is created: this can be large and if <code>simple = TRUE</code> this is avoided by sampling separately for each replication, which is slower but uses less memory.
<code>...</code>	Other named arguments for <code>statistic</code> which are passed unchanged each time it is called. Any such arguments to <code>statistic</code> should follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial matching to arguments of <code>boot</code> listed above, and that arguments named <code>X</code> and <code>FUN</code> cause conflicts in some versions of <b>boot</b> (but not this one).
<code>parallel</code>	The type of parallel operation to be used (if any). If missing, the default is taken from the option <code>"boot.parallel"</code> (and if that is not set, <code>"no"</code> ).
<code>ncpus</code>	integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.
<code>cl</code>	An optional <b>parallel</b> or <b>snow</b> cluster for use if <code>parallel = "snow"</code> . If not supplied, a cluster on the local machine is created for the duration of the <code>boot</code> call.

## Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. `statistic` is treated as a black box by the `boot` function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function `ran.gen` which will return a simulated data set from the observed data set and a set of parameter estimates specified in `mle`.

**Value**

The returned value is an object of class "boot", containing the following components:

<code>t0</code>	The observed value of <code>statistic</code> applied to <code>data</code> .
<code>t</code>	A matrix with <code>sum(R)</code> rows each of which is a bootstrap replicate of the result of calling <code>statistic</code> .
<code>R</code>	The value of <code>R</code> as passed to <code>boot</code> .
<code>data</code>	The data as passed to <code>boot</code> .
<code>seed</code>	The value of <code>.Random.seed</code> when <code>boot</code> started work.
<code>statistic</code>	The function <code>statistic</code> as passed to <code>boot</code> .
<code>sim</code>	Simulation type used.
<code>stype</code>	Statistic type as passed to <code>boot</code> .
<code>call</code>	The original call to <code>boot</code> .
<code>strata</code>	The strata used. This is the vector passed to <code>boot</code> , if it was supplied or a vector of ones if there were no strata. It is not returned if <code>sim</code> is "parametric".
<code>weights</code>	The importance sampling weights as passed to <code>boot</code> or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if <code>sim</code> is not one of "ordinary" or "balanced".
<code>pred.i</code>	If predictions are required ( <code>m &gt; 0</code> ) this is the matrix of indices at which predictions were calculated as they were passed to <code>statistic</code> . Omitted if <code>m</code> is 0 or <code>sim</code> is not "ordinary".
<code>L</code>	The influence values used when <code>sim</code> is "antithetic". If no such values were specified and <code>stype</code> is not "w" then <code>L</code> is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when <code>sim</code> is not "antithetic".
<code>ran.gen</code>	The random generator function used if <code>sim</code> is "parametric". This component is omitted for any other value of <code>sim</code> .
<code>mle</code>	The parameter estimates passed to <code>boot</code> when <code>sim</code> is "parametric". It is omitted for all other values of <code>sim</code> .

There are `c`, `plot` and `print` methods for this class.

**Parallel operation**

When `parallel = "multicore"` is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when `parallel = "snow"` is used: the worker processes are newly created R processes, and `statistic` needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when `statistic` is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for [jack.after.boot](#) where ancillary functions are nested inside the `statistic` function.) `parallel = "snow"` is primarily intended to be used on multi-core Windows machine where `parallel = "multicore"` is not available.

For most of the `boot` methods the resampling is done in the master process, but not if `simple = TRUE` nor `sim = "parametric"`. In those cases (or where `statistic` itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by [censboot](#) (`sim = "wiedr"`) and by most of the schemes

in `tsboot` (the exceptions being `sim == "fixed"` and `sim == "geom"` with the default `ran.gen`).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with `parallel = "multicore"` or `parallel = "snow"` using the default cluster, a second approach is used if `RNGkind("L'Ecuyer-CMRG")` has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if `ncpus` is unchanged, and for `parallel = "multicore"` if `parallel::mc.reset.stream()` is called: see the examples for `mclapply`.

Note that loading the **parallel** namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
}
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
boot(grav1, diff.means, R = 999, stype = "f", strata = grav1[,2])

# In this example we show the use of boot in a prediction from
# regression based on the nuclear data. This example is taken
# from Example 6.8 of Davison and Hinkley (1997). Notice also
# that two extra arguments to 'statistic' are passed through boot.
nuke <- nuclear[, c(1, 2, 5, 7, 8, 10, 11)]
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)

# We set up a new data frame with the data, the standardized
# residuals and the fitted values for use in the bootstrap.
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))

# Now we want a prediction of plant number 32 but at date 73.00
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
                      ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)

nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
  lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
             data = dat)
  pred.b <- predict(lm.b, x.pred)
  c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}

nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
                 fit.pred = new.fit, x.pred = new.data)
# The bootstrap prediction squared error would then be found by
mean(nuke.boot$t[, 8]^2)
# Basic bootstrap prediction limits would be
new.fit - sort(nuke.boot$t[, 8])[c(975, 25)]

# Finally a parametric bootstrap. For this example we shall look
# at the air-conditioning data. In this example our aim is to test
# the hypothesis that the true value of the index is 1 (i.e. that
# the data come from an exponential distribution) against the
# alternative that the data come from a gamma distribution with
# index not equal to 1.
air.fun <- function(data) {
  ybar <- mean(data$hours)
  para <- c(log(ybar), mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
  }
}

```

```

    khat <- nlm(ll, ybar^2/var(data$hours))$estimate
    c(ybar, khat)
  }

  air.rg <- function(data, mle) {
    # Function to generate random exponential variates.
    # mle will contain the mean of the original data
    out <- data
    out$hours <- rexp(nrow(out), 1/mle)
    out
  }

  air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
    ran.gen = air.rg, mle = mean(aircondit$hours))

  # The bootstrap p-value can then be approximated by
  sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

```

---

boot.array	<i>Bootstrap Resampling Arrays</i>
------------	------------------------------------

---

## Description

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

## Usage

```
boot.array(boot.out, indices)
```

## Arguments

<code>boot.out</code>	An object of class "boot" returned by one of the generation functions for such an object.
<code>indices</code>	A logical argument which specifies whether to return the frequency array or the raw index array. The default is <code>indices=FALSE</code> unless <code>boot.out</code> was created by <code>tsboot</code> in which case the default is <code>indices=TRUE</code> .

## Details

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

### Value

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

### Side Effects

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

### See Also

`boot`, `censboot`, `freq.array`, `tilt.boot`, `tsboot`

### Examples

```
# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)
```

---

boot.ci

*Nonparametric Bootstrap Confidence Intervals*

---

### Description

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

### Usage

```
boot.ci(boot.out, conf = 0.95, type = "all",
        index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
        var.t = NULL, t0 = NULL, t = NULL, L = NULL,
        h = function(t) t, hdot = function(t) rep(1,length(t)),
        hinv = function(t) t, ...)
```

## Arguments

<code>boot.out</code>	An object of class "boot" containing the output of a bootstrap calculation.
<code>conf</code>	A scalar or vector containing the confidence level(s) of the required interval(s).
<code>type</code>	A vector of character strings representing the type of intervals required. The value should be any subset of the values <code>c("norm", "basic", "stud", "perc", "bca")</code> or simply "all" which will compute all five types of intervals.
<code>index</code>	This should be a vector of length 1 or 2. The first element of <code>index</code> indicates the position of the variable of interest in <code>boot.out\$t0</code> and the relevant column in <code>boot.out\$t</code> . The second element indicates the position of the variance of the variable of interest. If both <code>var.t0</code> and <code>var.t</code> are supplied then the second element of <code>index</code> (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in <code>boot.out\$t0</code> ).
<code>var.t0</code>	If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t0</code> defaults to <code>boot.out\$t0[index[2]]</code> otherwise <code>var.t0</code> is undefined. For studentized intervals <code>var.t0</code> must be defined. For the normal approximation, if <code>var.t0</code> is undefined it defaults to <code>var(t)</code> . If a transformation is supplied through the argument <code>h</code> then <code>var.t0</code> should be the variance of the untransformed statistic.
<code>var.t</code>	This is a vector (of length <code>boot.out\$R</code> ) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t</code> defaults to <code>boot.out\$t[,index[2]]</code> , otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument <code>h</code> then <code>var.t</code> should be the variance of the untransformed bootstrap statistics.
<code>t0</code>	The observed value of the statistic of interest. The default value is <code>boot.out\$t0[index[1]]</code> . Specification of <code>t0</code> and <code>t</code> allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions <code>h</code> , <code>hdot</code> , and <code>hinv</code> below.
<code>t</code>	The bootstrap replicates of the statistic of interest. It must be a vector of length <code>boot.out\$R</code> . It is an error to supply one of <code>t0</code> or <code>t</code> but not the other. Also if studentized intervals are required and <code>t0</code> and <code>t</code> are supplied then so should be <code>var.t0</code> and <code>var.t</code> . The default value is <code>boot.out\$t[,index]</code> .
<code>L</code>	The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter <code>h</code> then <code>L</code> should be the influence values for <code>t</code> ; the values for <code>h(t)</code> are derived from these and <code>hdot</code> within the function. If <code>L</code> is not supplied then the values are calculated using <code>empinf</code> if they are needed.
<code>h</code>	A function defining a transformation. The intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. <code>h(c(t1,t2,t3))</code> should return <code>c(h(t1),h(t2),h(t3))</code> . The default is the identity function.

hdot	A function of one argument returning the derivative of $h$ . It is a required argument if $h$ is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of $h(t_0)$ and $h(t)$ using the delta method, and also for finding the empirical influence values for BCa intervals. Like $h$ it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.
hinv	A function, like $h$ , which returns the inverse of $h$ . It is used to transform the intervals calculated on the scale of $h(t)$ back to the original scale. The default is the identity function. If $h$ is supplied but $hinv$ is not, then the intervals returned will be on the transformed scale.
...	Any extra arguments that <code>boot.out\$statistic</code> is expecting. These arguments are needed only if BCa intervals are required and $L$ is not supplied since in that case $L$ is calculated through a call to <code>empinf</code> which calls <code>boot.out\$statistic</code> .

### Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function `boot` must be run prior to running this function to create the object to be passed as `boot.out`.

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the  $R$  values in `boot.out` a warning is generated and such intervals should not be considered reliable.

### Value

An object of type `"bootci"` which contains the intervals. It has components

<code>R</code>	The number of bootstrap replicates on which the intervals were based.
<code>t0</code>	The observed value of the statistic on the same scale as the intervals.
<code>call</code>	The call to <code>boot.ci</code> which generated the object. It will also contain one or more of the following components depending on the value of <code>type</code> used in the call to <code>bootci</code> .
<code>normal</code>	A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
<code>basic</code>	The intervals calculated using the basic bootstrap method.
<code>student</code>	The intervals calculated using the studentized bootstrap method.
<code>percent</code>	The intervals calculated using the bootstrap percentile method.
<code>bca</code>	The intervals calculated using the adjusted bootstrap percentile (BCa) method. These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

```

brambles

*Spatial Location of Bramble Canes*

### Description

The `brambles` data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

### Usage

```
brambles
```

### Format

This data frame contains the following columns:

- `x` The x coordinate of the position of the cane in the plot.
- `y` The y coordinate of the position of the cane in the plot.
- `age` The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

### Source

The data were obtained from

Diggle, P.J. (1983) *Statistical Analysis of Spatial Point Patterns*. Academic Press.

### References

`breslow`*Smoking Deaths Among Doctors*

---

## Description

The `breslow` data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The `breslow` data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

## Usage

```
breslow
```

## Format

This data frame contains the following columns:

`age` The mid-point of the 10 year age-group for the doctors.

`smoke` An indicator of whether the doctors smoked (1) or not (0).

`n` The number of person-years in the category.

`y` The number of deaths attributed to coronary artery disease.

`ns` The number of smoker years in the category (`smoke*n`).

## Source

The data were obtained from

Breslow, N.E. (1985) Cohort Analysis in Epidemiology. In *A Celebration of Statistics* A.C. Atkinson and S.E. Fienberg (editors), 109–143. Springer-Verlag.

`calcium`*Calcium Uptake Data*

---

**Description**

The `calcium` data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

**Usage**

```
calcium
```

**Format**

This data frame contains the following columns:

`time` The time (in minutes) that the cells were suspended in the solution.

`cal` The amount of calcium uptake (nmoles/mg).

**Source**

The data were obtained from

Rawlings, J.O. (1988) *Applied Regression Analysis*. Wadsworth and Brooks/Cole Statistics/Probability Series.

**References**

---

`cane`*Sugar-cane Disease Data*

---

**Description**

The `cane` data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

**Usage**

```
cane
```

**Format**

This data frame contains the following columns:

- `n` The total number of shoots in each plot.
- `r` The number of diseased shoots.
- `x` The number of pieces of the stems, out of 50, planted in each plot.
- `var` A factor indicating the variety of sugar-cane in each plot.
- `block` A factor for the blocks.

**Details**

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvão da cana-de-açúcar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

**Source**

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de São Paulo, Brazil.

**References**

capability

*Simulated Manufacturing Process Data*

---

**Description**

The `capability` data frame has 75 rows and 1 column.

The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

**Usage**

```
capability
```

**Format**

This data frame contains the following column:

- `y` The simulated measurements.

**Source**

The data were obtained from

Bissell, A.F. (1990) How reliable is your capability index? *Applied Statistics*, **39**, 331–340.

catsM

*Weight Data for Domestic Cats*

---

## Description

The `catsM` data frame has 97 rows and 3 columns.

144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The `catsM` data frame consists of the data for the male cats. The full data are in dataset `cats` in package `MASS`.

## Usage

`cats`

## Format

This data frames contain the following columns:

`Sex` A factor for the sex of the cat (levels are F and M).

`Bwt` Body weight in kg.

`Hwt` Heart weight in g.

## Source

The data were obtained from

Fisher, R.A. (1947) The analysis of covariance method for the relation between a part and the whole. *Biometrics*, **3**, 65–68.

`cav`*Position of Muscle Caveolae*

---

**Description**

The `cav` data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65µm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset `caveolae.dat` in the **spatial** package by B.D. Ripley (1994).

**Usage**

```
cav
```

**Format**

This data frame contains the following columns:

- `x` The x coordinate of the caveola's position in the region.
- `y` The y coordinate of the caveola's position in the region.

---

`cd4`*CD4 Counts for HIV-Positive Patients*

---

**Description**

The `cd4` data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

**Usage**

```
cd4
```

**Format**

This data frame contains the following columns:

`baseline` The CD4 counts (in 100's) on admission to the trial.  
`oneyear` The CD4 counts (in 100's) after one year of treatment with the new drug.

**Source**

The data were obtained from

DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science*, **11**, 189–228.

<code>censboot</code>	<i>Bootstrap for Censored Data</i>
-----------------------	------------------------------------

---

**Description**

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

**Usage**

```
censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
          sim = "ordinary", cox = NULL, index = c(1, 2), ...,
          parallel = c("no", "multicore", "snow"),
          ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

## Arguments

<code>data</code>	The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for <code>sim = "weird"</code> when it should only have two columns - the times and censoring indicators. The columns of <code>data</code> referenced by the components of <code>index</code> are taken to be the times and censoring indicators.
<code>statistic</code>	A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the <code>...</code> argument. In the case of <code>sim = "weird"</code> , the data passed to <code>statistic</code> only contains the times and censoring indicator regardless of the actual number of columns in <code>data</code> . In all other cases the data passed to <code>statistic</code> will be of the same form as the original data. When <code>sim = "weird"</code> , the actual number of observations in the resampled data sets may not be the same as the number in <code>data</code> . For this reason, if <code>sim = "weird"</code> and <code>strata</code> is supplied, <code>statistic</code> should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.
<code>R</code>	The number of bootstrap replicates.
<code>F.surv</code>	An object returned from a call to <code>survfit</code> giving the survivor function for the data. This is a required argument unless <code>sim = "ordinary"</code> or <code>sim = "model"</code> and <code>cox</code> is missing.
<code>G.surv</code>	Another object returned from a call to <code>survfit</code> but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to <code>survfit</code> . This is a required argument whenever <code>sim = "cond"</code> or when <code>sim = "model"</code> and <code>cox</code> is supplied.
<code>strata</code>	The strata used in the calls to <code>survfit</code> . It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When <code>sim = "weird"</code> only the strata for the survival distribution are used since the censoring times are considered fixed. When <code>sim = "ordinary"</code> , only one set of strata is used to stratify the observations, this is taken to be the first column of <code>strata</code> when it is a matrix.
<code>sim</code>	The simulation type. Possible types are <code>"ordinary"</code> (case resampling), <code>"model"</code> (equivalent to <code>"ordinary"</code> if <code>cox</code> is missing, otherwise it is model-based resampling), <code>"weird"</code> (the weird bootstrap - this cannot be used if <code>cox</code> is supplied), and <code>"cond"</code> (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).
<code>cox</code>	An object returned from <code>coxph</code> . If it is supplied, then <code>F.surv</code> should have been generated by a call of the form <code>survfit(cox)</code> .
<code>index</code>	A vector of length two giving the positions of the columns in <code>data</code> which correspond to the times and censoring indicators respectively.
<code>...</code>	Other named arguments which are passed unchanged to <code>statistic</code> each time it is called. Any such arguments to <code>statistic</code> must follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial

matching to arguments of `censboot` listed above, and that arguments named `X` and `FUN` cause conflicts in some versions of **boot** (but not this one).

`parallel`, `ncpus`, `cl`

See the help for `boot`.

## Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of `Inf` and conversely if it is uncensored it is given a nominal censoring time of `Inf`. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (`sim = "model"`) or from the conditional censoring distribution as in the previous paragraph (`sim = "cond"`).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and `sim` is either `"model"` or `"cond"` the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of `Inf`, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of `Inf` and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

When `parallel = "snow"` and `cl` is not supplied, `library(survival)` is run in each of the worker processes.

## Value

An object of class `"boot"` containing the following components:

<code>t0</code>	The value of <code>statistic</code> when applied to the original data.
<code>t</code>	A matrix of bootstrap replicates of the values of <code>statistic</code> .
<code>R</code>	The number of bootstrap replicates performed.
<code>sim</code>	The simulation type used. This will usually be the input value of <code>sim</code> unless that was <code>"model"</code> but <code>cox</code> was not supplied, in which case it will be <code>"ordinary"</code> .
<code>data</code>	The data used for the bootstrap. This will generally be the input value of <code>data</code> unless <code>sim = "weird"</code> , in which case it will just be the columns containing the times and the censoring indicators.

seed	The value of <code>.Random.seed</code> when <code>censboot</code> started work.
statistic	The input value of <code>statistic</code> .
strata	The strata used in the resampling. When <code>sim = "ordinary"</code> this will be a vector which stratifies the observations, when <code>sim = "weird"</code> it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
call	The original call to <code>censboot</code> .

channing

Channing House Data

---

## Description

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

## Usage

```
channing
```

## Format

This data frame contains the following columns:

**sex** A factor for the sex of each resident ("Male" or "Female").

**entry** The residents age (in months) on entry to the centre

**exit** The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.

**time** The length of time (in months) that the resident spent at Channing House.  
(time=exit-entry)

**cens** The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

`claridge`*Genetic Links to Left-handedness*

---

**Description**

The `claridge` data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

**Usage**

```
claridge
```

**Format**

This data frame contains the following columns:

`dnan` The genetic measurement on each woman's DNA.

`hand` The measure of left-handedness on an integer scale from 1 to 8.

**Source**

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

<code>co.transfer</code>	<i>Carbon Monoxide Transfer</i>
--------------------------	---------------------------------

---

**Description**

The `co.transfer` data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

**Usage**

```
co.transfer
```

**Format**

This data frame contains the following columns:

- `entry` Carbon monoxide transfer factor on entry to hospital.
- `week` Carbon monoxide transfer one week after admittance to hospital.

**Source**

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E (1994) *A Handbook of Small Data Sets*. Chapman and Hall.

---

`coal`*Dates of Coal Mining Disasters*

---

**Description**

The `coal` data frame has 191 rows and 1 columns.

This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22 1962.

**Usage**

```
coal
```

**Format**

This data frame contains the following column:

`date` The date of the disaster. The integer part of `date` gives the year. The day is represented as the fraction of the year that had elapsed on that day.

**Source**

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

**References**

---

`control`*Control Variate Calculations*

---

**Description**

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

**Usage**

```
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL,  
        t = NULL, bias.adj = FALSE, alpha = NULL, ...)
```

**Arguments**

<code>boot.out</code>	A bootstrap output object returned from <code>boot</code> . The bootstrap replicates must have been generated using the usual nonparametric bootstrap.
<code>L</code>	The empirical influence values for the statistic of interest. If <code>L</code> is not supplied then <code>empinf</code> is called to calculate them from <code>boot.out</code> .
<code>distn</code>	If present this must be the output from <code>smooth.spline</code> giving the distribution function of the linear approximation. This is used only if <code>bias.adj</code> is <code>FALSE</code> . Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by <code>saddle.distn</code> .
<code>index</code>	The index of the variable of interest in the output of <code>boot.out\$statistic</code> .
<code>t0</code>	The observed value of the statistic of interest on the original data set <code>boot.out\$data</code> . This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input value is ignored if <code>t</code> is not also supplied. The default value is <code>boot.out\$t0[index]</code> .
<code>t</code>	The bootstrap replicate values of the statistic of interest. This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input is ignored if <code>t0</code> is not supplied also. The default value is <code>boot.out\$t[, index]</code> .
<code>bias.adj</code>	A logical variable which if <code>TRUE</code> specifies that the adjusted bias estimate using post-simulation balance is all that is required. If <code>bias.adj</code> is <code>FALSE</code> (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.
<code>alpha</code>	The alpha levels for the required quantiles if <code>bias.adj</code> is <code>FALSE</code> .
<code>...</code>	Any additional arguments that <code>boot.out\$statistic</code> requires. These are passed unchanged every time <code>boot.out\$statistic</code> is called. <code>boot.out\$statistic</code> is called once if <code>bias.adj</code> is <code>TRUE</code> , otherwise it may be called by <code>empinf</code> for empirical influence calculations if <code>L</code> is not supplied.

**Details**

If `bias.adj` is `FALSE` then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation  $T^* = Tl^* + (T^* - Tl^*)$ , moment estimates can be found. For quantile estimation the distribution of the linear approximation to `t` is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of `t` and hence to estimate the bootstrap quantiles of `t`.

**Value**

If `bias.adj` is `TRUE` then the returned value is the adjusted bias estimate.

If `bias.adj` is `FALSE` then the returned value is a list with the following components

<code>L</code>	The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by <code>empinf</code> .
<code>tL</code>	The linear approximations to the bootstrap replicates <code>t</code> of the statistic of interest.
<code>bias</code>	The control estimate of bias using the linear approximation to <code>t</code> as a control variate.
<code>var</code>	The control estimate of variance using the linear approximation to <code>t</code> as a control variate.

k3	The control estimate of the third cumulant using the linear approximation to $t$ as a control variate.
quantiles	A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to $t$ as a control variate.
distn	An output object from <code>smooth.spline</code> describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to $t$ . If <code>distn</code> was supplied on input then this is the same as the input otherwise it is calculated by a call to <code>saddle.distn</code> .

## Examples

```
# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{
  m <- mean(d$hours[i])
  n <- nrow(d)
  v <- (n-1)*var(d$hours[i])/n^2
  c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
  t = log(air.boot$t[, 2]))
```

---

corr

*Correlation Coefficient*

---

## Description

Calculates the weighted correlation given a data set and a set of weights.

## Usage

```
corr(d, w = rep(1, nrow(d))/nrow(d))
```

**Arguments**

<code>d</code>	A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.
<code>w</code>	A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so <code>sum(w)</code> need not equal 1.

**Details**

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

**Value**

The correlation coefficient between `d[, 1]` and `d[, 2]`.

**See Also**

[cor](#)

---

cum3

*Calculate Third Order Cumulants*

---

**Description**

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

**Usage**

```
cum3(a, b = a, c = a, unbiased = TRUE)
```

**Arguments**

<code>a</code>	A vector of observations.
<code>b</code>	Another vector of observations, if not supplied it is set to the value of <code>a</code> . If supplied then it must be the same length as <code>a</code> .
<code>c</code>	Another vector of observations, if not supplied it is set to the value of <code>a</code> . If supplied then it must be the same length as <code>a</code> .
<code>unbiased</code>	A logical value indicating whether the unbiased estimator should be used.

**Details**

The unbiased estimator uses a multiplier of  $n / ((n-1) * (n-2))$  where  $n$  is the sample size, if `unbiased` is `FALSE` then a multiplier of  $1/n$  is used. This is multiplied by `sum((a-mean(a)) * (b-mean(b)) * (c-mean(c)))` to give the required estimate.

**Value**

The required estimate.

## Description

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

## Usage

```
cv.glm(data, glmfit, cost, K)
```

## Arguments

<code>data</code>	A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.
<code>glmfit</code>	An object of class "glm" containing the results of a generalized linear model fitted to <code>data</code> .
<code>cost</code>	A function of two vector arguments specifying the cost function for the cross-validation. The first argument to <code>cost</code> should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. <code>cost</code> must return a non-negative scalar value. The default is the average squared error function.
<code>K</code>	The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of <code>K</code> must be such that all groups are of approximately equal size. If the supplied value of <code>K</code> does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of <code>K</code> used. The default is to set <code>K</code> equal to the number of observations in <code>data</code> which gives the usual leave-one-out cross-validation.

## Details

The data is divided randomly into `K` groups. For each group the generalized linear model is fit to `data` omitting that group, then the function `cost` is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When `K` is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When `K` is less than the number of observations the `K` splits to be used are found by randomly partitioning the data into `K` groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in `delta` is the estimate adjusted by this method.

## Value

The returned value is a list with the following components.

<code>call</code>	The original call to <code>cv.glm</code> .
<code>K</code>	The value of <code>K</code> used for the K-fold cross validation.

delta	A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation.
seed	The value of <code>.Random.seed</code> when <code>cv.glm</code> was called.

### Side Effects

The value of `.Random.seed` is updated.

---

darwin*Darwin's Plant Height Differences*

---

**Description**

The `darwin` data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

**Usage**

```
darwin
```

**Format**

This data frame contains the following column:

`y` The difference in heights for the pairs of plants (in units of 0.125 inches).

**Source**

The data were obtained from

Fisher, R.A. (1935) *Design of Experiments*. Oliver and Boyd.

downs.bc

*Incidence of Down's Syndrome in British Columbia*

---

**Description**

The `downs.bc` data frame has 30 rows and 3 columns.

Down's syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down's syndrome is highly dependent on the mother's age and rises sharply after age 30. In the 1960's a large scale study of the effect of maternal age on the incidence of Down's syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

**Usage**

`downs.bc`

**Format**

This data frame contains the following columns:

**age** The average age of all mothers in the age category.

**m** The total number of live births to mothers in the age category.

**r** The number of cases of Down's syndrome.

**Source**

The data were obtained from

Geyer, C.J. (1991) Constrained maximum likelihood exemplified by isotonic convex logistic regression. *Journal of the American Statistical Association*, **86**, 717–724.

---

ducks*Behavioral and Plumage Characteristics of Hybrid Ducks*

---

**Description**

The `ducks` data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

**Usage**

```
ducks
```

**Format**

This data frame contains the following columns:

`plumage` The index of physical appearance based on the plumage of individual ducks.

`behaviour` The index of behavioural characteristics of the ducks.

**Source**

The data were obtained from

Larsen, R.J. and Marx, M.L. (1986) *An Introduction to Mathematical Statistics and its Applications* (Second Edition). Prentice-Hall.

**References**

---

EEF.profile*Empirical Likelihoods*

---

**Description**

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

**Usage**

```
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
            u = function(y, t) y - t)
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
           u = function(y, t) y - t)
```

**Arguments**

<code>y</code>	A vector or matrix of data
<code>tmin</code>	The minimum value of the range over which the likelihood should be computed. This must be larger than <code>min(y)</code> .
<code>tmax</code>	The maximum value of the range over which the likelihood should be computed. This must be smaller than <code>max(y)</code> .
<code>n.t</code>	The number of points between <code>tmin</code> and <code>tmax</code> at which the value of the log-likelihood should be computed.
<code>u</code>	A function of the data and the parameter.

**Details**

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package `boot` for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the `boot` package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen's empirical likelihood home page at the URL <http://statistics.stanford.edu/~owen/empirical/>.

**Value**

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

empinf

*Empirical Influence Values***Description**

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

**Usage**

```
empinf(boot.out = NULL, data = NULL, statistic = NULL,
       type = NULL, stype = NULL, index = 1, t = NULL,
       strata = rep(1, n), eps = 0.001, ...)
```

**Arguments**

<code>boot.out</code>	A bootstrap object created by the function <code>boot</code> . If <code>type</code> is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of <code>data</code> , <code>statistic</code> , <code>stype</code> , and <code>strata</code> are taken from the components of <code>boot.out</code> and any values passed to <code>empinf</code> directly are ignored.
<code>data</code>	A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if <code>boot.out</code> is not supplied. If <code>boot.out</code> is supplied then <code>data</code> is set to <code>boot.out\$data</code> and any value supplied is ignored.
<code>statistic</code>	The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of <code>stype</code> . Any other arguments that it takes must be supplied to <code>empinf</code> and will be passed to <code>statistic</code> unchanged. This is a required argument if <code>boot.out</code> is not supplied, otherwise its value is taken from <code>boot.out</code> and any value supplied here will be ignored.
<code>type</code>	The calculation type to be used for the empirical influence values. Possible values of <code>type</code> are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If <code>t</code> is supplied then the default value of <code>type</code> is "reg" and <code>boot.out</code> should be present so that its frequency array can be found. If <code>t</code> is not supplied then if <code>stype</code> is "w", the default value of <code>type</code> is "inf"; otherwise, if <code>boot.out</code> is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for <code>type</code> to be "reg" if <code>boot.out</code> is missing or to be "inf" if <code>stype</code> is not "w".
<code>stype</code>	A character variable giving the nature of the second argument to <code>statistic</code> . It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If <code>boot.out</code> is supplied the value of <code>stype</code> is set to <code>boot.out\$stype</code> and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If <code>type</code> is "inf" then <code>stype</code> MUST be "w".

<code>index</code>	An integer giving the position of the variable of interest in the output of <code>statistic</code> .
<code>t</code>	A vector of length <code>boot.out\$R</code> which gives the bootstrap replicates of the statistic of interest. <code>t</code> is used only when <code>type</code> is <code>reg</code> and it defaults to <code>boot.out\$t[, index]</code> .
<code>strata</code>	An integer vector or a factor specifying the strata for multi-sample problems. If <code>boot.out</code> is supplied the value of <code>strata</code> is set to <code>boot.out\$strata</code> . Otherwise it is an optional argument which has default corresponding to the single sample situation.
<code>eps</code>	This argument is used only if <code>type</code> is <code>"inf"</code> . In that case the value of epsilon to be used for numerical differentiation will be <code>eps</code> divided by the number of observations in <code>data</code> .
<code>...</code>	Any other arguments that <code>statistic</code> takes. They will be passed unchanged to <code>statistic</code> every time that it is called.

### Details

If `type` is `"inf"` then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. `stype` is `"w"`). If `type` is `"jack"` then the usual leave-one-out jackknife estimates of the empirical influence are returned. If `type` is `"pos"` then the positive (include-one-twice) jackknife values are used. If `type` is `"reg"` then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of `statistic` on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to `boot.array`. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

### Value

A vector of the empirical influence values of `statistic` applied to `data`. The values will be in the same order as the observations in `data`.

### Warning

All arguments to `empinf` must be passed using the `name = value` convention. If this is not followed then unpredictable errors can occur.

# Since the statistic of interest is a function of the bootstrap
# statistics, we must calculate the bootstrap replicates and pass
# them to empinf using the t argument.
grav.z <- (grav.boot$t[,1]-grav.boot$t0[1])/sqrt(grav.boot$t[,2])
empinf(boot.out = grav.boot, t = grav.z)
```

**Description**

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

**Usage**

```
envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))
```

## Arguments

<code>boot.out</code>	An object of class "boot" for which <code>boot.out\$t</code> contains the replicates of the curve at a number of fixed points.
<code>mat</code>	A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if <code>boot.out</code> is not supplied and is set to <code>boot.out\$t</code> otherwise.
<code>level</code>	The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope.
<code>index</code>	The numbers of the columns of <code>mat</code> which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.

## Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

## Value

A list with the following components :

<code>point</code>	A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated.
<code>overall</code>	A matrix similar to <code>point</code> but containing the envelope which controls the overall error.
<code>k.pt</code>	The quantiles used for the pointwise envelope.
<code>err.pt</code>	A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.
<code>k.ov</code>	The quantiles used for the overall envelope.
<code>err.ov</code>	A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.
<code>err.nom</code>	A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.

lines(grav.qq$x, grav.env$overall[2, ], lty = 1)
```

exp.tilt

*Exponential Tilting*

## Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

## Usage

```
exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL,
        strata = rep(1, length(L)))
```

## Arguments

<code>L</code>	The empirical influence values for the statistic of interest based on the observed data. The length of <code>L</code> should be the same as the size of the original data set. Typically <code>L</code> will be calculated by a call to <code>empinf</code> .
<code>theta</code>	The value at which the tilted distribution is to be centred. This is not required if <code>lambda</code> is supplied but is needed otherwise.
<code>t0</code>	The current value of the statistic. The default is that the statistic equals 0.
<code>lambda</code>	The Lagrange multiplier(s). For each value of <code>lambda</code> a multinomial distribution is found with probabilities proportional to $\exp(\text{lambda} * L)$ . In general <code>lambda</code> is not known and so <code>theta</code> would be supplied, and the corresponding value of <code>lambda</code> found. If both <code>lambda</code> and <code>theta</code> are supplied then <code>lambda</code> is ignored and the multipliers for tilting to <code>theta</code> are found.
<code>strata</code>	A vector or factor of the same length as <code>L</code> giving the strata for the observed data and the empirical influence values <code>L</code> .

## Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean `theta`. The weights chosen to achieve this are given by `p[j]` proportional to  $\exp(\lambda L[j]/n)$ , where `n` is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions `imp.prob` or `imp.quantile` to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of `smooth.f`. The function `tilt.boot` uses `exp.tilt` or `smooth.f` to find the weights for a tilted bootstrap.

## Value

A list with the following components :

<code>p</code>	The tilted probabilities. There will be <code>m</code> distributions where <code>m</code> is the length of <code>theta</code> (or <code>lambda</code> if supplied). If <code>m</code> is 1 then <code>p</code> is a vector of length <code>(L)</code> probabilities. If <code>m</code> is greater than 1 then <code>p</code> is a matrix with <code>m</code> rows, each of which contain length <code>(L)</code> probabilities. In this case the vector <code>p[i, ]</code> is the distribution tilted to <code>theta[i]</code> . <code>p</code> is in the form required by the argument <code>weights</code> of the function <code>boot</code> for importance resampling.
<code>lambda</code>	The Lagrange multiplier used in the equation to determine the tilted probabilities. <code>lambda</code> is a vector of the same length as <code>theta</code> .
<code>theta</code>	The values of <code>theta</code> to which the distributions have been tilted. In general this will be the input value of <code>theta</code> but if <code>lambda</code> was supplied then this is the vector of the corresponding <code>theta</code> values.

                 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
boot(grav1, grav.fun, R = 499, stype = "w", weights = grav.tilt$p,
     strata = grav1[,2], orig = grav.z0[1])

```

fir

*Counts of Balsam-fir Seedlings*

## Description

The `fir` data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

## Usage

```
fir
```

## Format

This data frame contains the following columns:

`count` The number of seedlings in the quadrant.

`row` The row number of the quadrant.

`col` The quadrant number within the row.

## Source

---

freq.array

*Bootstrap Frequency Arrays*

---

### Description

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

### Usage

```
freq.array(i.array)
```

### Arguments

`i.array` This will be an matrix of integers between 1 and `n`, where `n` is the number of observations in a data set. The matrix will have `n` columns and `R` rows where `R` is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`.

### Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

frets

*Head Dimensions in Brothers*

---

### Description

The `frets` data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

### Usage

```
frets
```

**Format**

This data frame contains the following columns:

- l1 The head length of the eldest son.
- b1 The head breadth of the eldest son.
- l2 The head length of the second son.
- b2 The head breadth of the second son.

**Source**

The data were obtained from

Frets, G.P. (1921) Heredity of head form in man. *Genetica*, **3**, 193.

---

glm.diag

---

*Generalized Linear Model Diagnostics*

---

**Description**

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

**Usage**

```
glm.diag(glmfit)
```

**Arguments**

glmfit                  glmfit is a glm.object - the result of a call to glm()

**Value**

Returns a list with the following components

- |      |  |
|------|--|
| res  | The vector of jackknife deviance residuals.  |
| rd   | The vector of standardized deviance residuals.   |
| rp   | The vector of standardized Pearson residuals.  |
| cook | The vector of approximate Cook statistics.   |
| h    | The vector of leverages of the observations.   |
| sd   | The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1. |

**Note**

See the help for `glm.diag.plots` for an example of the use of `glm.diag`.

**References**

Davison, A.C. and Snell, E.J. (1991) Residuals and diagnostics. In *Statistical Theory and Modelling: In Honour of Sir David Cox*. D.V. Hinkley, N. Reid and E.J. Snell (editors), 83–106. Chapman and Hall.

---

glm.diag.plots	<i>Diagnostics plots for generalized linear models</i>
----------------	--

---

**Description**

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

**Usage**

```
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL,
              iden = FALSE, labels = NULL, ret = FALSE)
```

**Arguments**

glmfit	glm.object : the result of a call to <code>glm()</code>
glmdiag	Diagnostics of <code>glmfit</code> obtained from a call to <code>glm.diag</code> . If it is not supplied then it is calculated.
subset	Subset of data for which <code>glm</code> fitting performed: should be the same as the <code>subset</code> option used in the call to <code>glm()</code> which generated <code>glmfit</code> . Needed only if the <code>subset=</code> option was used in the call to <code>glm</code> .
iden	A logical argument. If <code>TRUE</code> then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke <code>identify()</code> on that plot. After exiting <code>identify()</code> , the user is again prompted, this loop continuing until the user responds to the prompt with 0. If <code>iden</code> is <code>FALSE</code> (default) the user cannot interact with the plots.
labels	A vector of labels for use with <code>identify()</code> if <code>iden</code> is <code>TRUE</code> . If it is not supplied then the labels are derived from <code>glmfit</code> .
ret	A logical argument indicating if <code>glmdiag</code> should be returned. The default is <code>FALSE</code> .

## Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at  $8/(n-2p)$  where  $n$  is the number of observations and  $p$  is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at  $2p/(n-2p)$  and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

## Value

If `ret` is `TRUE` then the value of `glm.diag` is returned otherwise there is no returned value.

## Side Effects

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is `TRUE`, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

gravity	<i>Acceleration Due to Gravity</i>
---------	------------------------------------

---

**Description**

The `gravity` data frame has 81 rows and 2 columns.

The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity,  $g$ , at Washington. Each experiment produced a number of replicate estimates of  $g$  using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

**Usage**

`gravity`

**Format**

This data frame contains the following columns:

`g` The deviation of the estimate from 980.000 centimetres per second squared.

`series` A factor describing from which experiment the estimate was derived.

**Source**

The data were obtained from

Cressie, N. (1982) Playing safe with misweighted means. *Journal of the American Statistical Association*, **77**, 754–759.

hirose	<i>Failure Time of PET Film</i>
--------	---------------------------------

---

**Description**

The `hirose` data frame has 44 rows and 3 columns.

PET film is used in electrical insulation. In this accelerated life test the failure times for 44 samples in gas insulated transformers. 4 different voltage levels were used.

**Usage**

```
hirose
```

**Format**

This data frame contains the following columns:

`volt` The voltage (in kV).

`time` The failure or censoring time in hours.

`cens` The censoring indicator; 1 means right-censored data.

**Source**

The data were obtained from

Hirose, H. (1993) Estimation of threshold stress in accelerated life-testing. *IEEE Transactions on Reliability*, **42**, 650–657.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

---

Imp.Estimates

---

Importance Sampling Estimates

---

**Description**

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

**Usage**

```
imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
            w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
         t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
            t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
```

**Arguments**

<code>boot.out</code>	A object of class "boot" generated by a call to <code>boot</code> or <code>tilt.boot</code> . Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights <code>w</code> are not supplied then <code>boot.out</code> is a required argument. It is also required if <code>t</code> is not supplied.
<code>alpha</code>	The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.
<code>index</code>	The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This is not used if the argument <code>t</code> is supplied.

<code>t0</code>	The values at which tail probability estimates are required. For each value <code>t0[i]</code> the function will estimate the bootstrap cdf evaluated at <code>t0[i]</code> . If <code>imp.prob</code> is called without the argument <code>t0</code> then the bootstrap cdf evaluated at the observed value of the statistic is found.
<code>t</code>	The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object <code>boot.out</code> but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in <code>boot.out</code> ). Either <code>boot.out</code> or <code>t</code> must be supplied.
<code>w</code>	The importance resampling weights for the bootstrap replicates. If they are not supplied then <code>boot.out</code> must be supplied, in which case the importance weights are calculated by a call to <code>imp.weights</code> .
<code>def</code>	A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if <code>w</code> is missing and it is passed unchanged to <code>imp.weights</code> to calculate <code>w</code> .
<code>q</code>	A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights <code>w</code> so this argument is ignored if <code>w</code> is supplied. If <code>w</code> is missing then <code>q</code> is passed as an argument to <code>imp.weights</code> and used to find <code>w</code> .

### Value

A list with the following components :

<code>alpha</code>	The alpha levels used for the quantiles, if <code>imp.quantile</code> is used.
<code>t0</code>	The values at which the tail probabilities are estimated, if <code>imp.prob</code> is used.
<code>raw</code>	The raw importance resampling estimates. For <code>imp.moments</code> this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For <code>imp.prob</code> , <code>raw</code> is of the same length as <code>t0</code> , and for <code>imp.quantile</code> it is of the same length as <code>alpha</code> .
<code>rat</code>	The ratio importance resampling estimates. In this method the weights <code>w</code> are rescaled to have average value one before they are used. The format of this vector is the same as <code>raw</code> .
<code>reg</code>	The regression importance resampling estimates. In this method the weights which are used are derived from a regression of $t \cdot w$ on $w$ . This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as <code>raw</code> .

```

---

imp.weights

*Importance Sampling Weights*

---

**Description**

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities  $p$  when estimates are required assuming that simulation was from an alternative distribution with probabilities  $q$ .

**Usage**

```
imp.weights(boot.out, def = TRUE, q = NULL)
```

## Arguments

<code>boot.out</code>	A object of class "boot" generated by <code>boot</code> or <code>tilt.boot</code> . Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.
<code>def</code>	A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in <code>boot.out</code> were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated.
<code>q</code>	A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. <code>q</code> must have length equal to the number of observations in the <code>boot.out\$data</code> and all elements of <code>q</code> must be positive.

## Details

The importance sampling weight for a bootstrap replicate with frequency vector  $\mathbf{f}$  is given by  $\text{prod}((q/p)^{\mathbf{f}})$ . This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities  $q$  even though, in fact, they came from the distribution  $p$ .

## Value

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities  $q$ .

## Note

See the example in the help for `imp.moments` for an example of using `imp.weights`.

---

inv.logit

*Inverse Logit Function*

---

**Description**

Given a numeric object return the inverse logit of the values.

**Usage**

```
inv.logit(x)
```

**Arguments**

`x` A numeric object. Missing values (NAs) are allowed.

**Details**

The inverse logit is defined by  $\exp(x) / (1 + \exp(x))$ . Values in `x` of `-Inf` or `Inf` return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

**Value**

An object of the same type as `x` containing the inverse logits of the input values.

**See Also**

islay

*Jura Quartzite Azimuths on Islay*

---

**Description**

The `islay` data frame has 18 rows and 1 columns.

Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

**Usage**

```
islay
```

**Format**

This data frame contains the following column:

`theta` The angle of the azimuth in degrees East of North.

## Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

---

jack.after.boot	<i>Jackknife-after-Bootstrap Plots</i>
-----------------	--

---

## Description

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

## Usage

```
jack.after.boot (boot.out, index = 1, t = NULL, L = NULL,
                useJ = TRUE, stinf = TRUE, alpha = NULL,
                main = "", ylab = NULL, ...)
```

## Arguments

boot.out	An object of class "boot" which would normally be created by a call to <a href="#">boot</a> . It should represent a nonparametric bootstrap. For reliable results <code>boot.out\$R</code> should be reasonably large.
index	The index of the statistic of interest in the output of <code>boot.out\$statistic</code> .
t	A vector of length <code>boot.out\$R</code> giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is <code>boot.out\$t[, index]</code> .
L	The empirical influence values for the statistic of interest. These are used only if <code>useJ</code> is <code>FALSE</code> . If they are not supplied and are needed, they are calculated by a call to <code>empinf</code> . If <code>L</code> is supplied then it is assumed that they are the infinitesimal jackknife values.
useJ	A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If <code>FALSE</code> the empirical influence values are used. The default is <code>TRUE</code> .
stinf	A logical variable indicating whether to standardize the jackknife values before plotting them. If <code>TRUE</code> then the jackknife values used are divided by their standard error.
alpha	The quantiles at which the plots are required. The default is <code>c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95)</code> .
main	A character string giving the main title for the plot.

ylab	The label for the Y axis. If the default values of <code>alpha</code> are used and <code>ylab</code> is not supplied then a label indicating which percentiles are plotted is used. If <code>alpha</code> is supplied then the default label will not say which percentiles were used.
...	Any extra arguments required by <code>boot.out\$statistic</code> . These are required only if <code>useJ</code> is <code>FALSE</code> and <code>L</code> is not supplied, in which case they are passed to <code>empinf</code> for use in calculation of the empirical influence values.

## Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If `useJ` is `TRUE` then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If `useJ` is `FALSE` then empirical influence values are calculated by calling `empinf`.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

## Value

There is no returned value but a plot is generated on the current graphics display.

## Side Effects

A plot is created on the current graphics device.

## Examples

```
# To draw the jackknife-after-bootstrap plot for the head size data as in
# Example 3.24 of Davison and Hinkley (1997)
frets.fun <- function(data, i) {
  pcorr <- function(x) {
    # Function to find the correlations and partial correlations between
    # the four measurements.
    v <- cor(x)
```

```

v.d <- diag(var(x))
iv <- solve(v)
iv.d <- sqrt(diag(iv))
iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
q <- NULL
n <- nrow(v)
for (i in 1:(n-1))
  q <- rbind( q, c(v[i, 1:i], iv[i, (i+1):n]) )
q <- rbind( q, v[n, ] )
diag(q) <- round(diag(q))
q
}
d <- data[i, ]
v <- pcorr(d)
c(v[1,], v[2,], v[3,], v[4,])
}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
# we will concentrate on the partial correlation between head breadth
# for the first son and head length for the second. This is the 7th
# element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)

```

k3.linear

*Linear Skewness Estimate***Description**

Estimates the skewness of a statistic from its empirical influence values.

**Usage**

```
k3.linear(L, strata = NULL)
```

**Arguments**

<code>L</code>	Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> .
<code>strata</code>	A numeric vector or factor specifying which observations (and hence which components of <code>L</code> ) come from which strata.

**Value**

The skewness estimate calculated from `L`.

**References**

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**See Also**

[empinf](#), [linear.approx](#), [var.linear](#)

## Examples

```
# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))
```

linear.approx

*Linear Approximation of Bootstrap Replicates*

## Description

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

## Usage

```
linear.approx(boot.out, L = NULL, index = 1, type = NULL,
              t0 = NULL, t = NULL, ...)
```

## Arguments

<code>boot.out</code>	An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function <code>boot</code> .
<code>L</code>	A vector containing the empirical influence values for the statistic of interest. If it is not supplied then <code>L</code> is calculated through a call to <code>empinf</code> .
<code>index</code>	The index of the variable of interest within the output of <code>boot.out\$statistic</code> .
<code>type</code>	This gives the type of empirical influence values to be calculated. It is not used if <code>L</code> is supplied. The possible types of empirical influence values are described in the help for <code>empinf</code> .
<code>t0</code>	The observed value of the statistic of interest. The input value is used only if one of <code>t</code> or <code>L</code> is also supplied. The default value is <code>boot.out\$t0[index]</code> . If <code>t0</code> is supplied but neither <code>t</code> nor <code>L</code> are supplied then <code>t0</code> is set to <code>boot.out\$t0[index]</code> and a warning is generated.
<code>t</code>	A vector of bootstrap replicates of the statistic of interest. If <code>t0</code> is missing then <code>t</code> is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in <code>L</code> ).
<code>...</code>	Any extra arguments required by <code>boot.out\$statistic</code> . These are needed if <code>L</code> is not supplied as they are used by <code>empinf</code> to calculate empirical influence values.

## Details

The linear approximation to a bootstrap replicate with frequency vector `f` is given by  $t_0 + \text{sum}(L * f) / n$  in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

## Value

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

lines.saddle.distn *Add a Saddlepoint Approximation to a Plot*

---

## Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

## Usage

```
## S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
      npts = 50, lty = 1, ...)
```

## Arguments

x	An object of class "saddle.distn" (see <a href="#">saddle.distn.object</a> representing a saddlepoint approximation to a distribution.
dens	A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.
h	Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.
J	When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must be the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list.
npts	The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.
lty	The line type to be used.
...	Any additional arguments to h and J.

## Details

The function uses `smooth.spline` to produce the saddlepoint curve. When `dens=TRUE` the spline is on the log scale and when `dens=FALSE` it is on the probit scale.

## Value

`sad.d` is returned invisibly.

## Side Effects

A line is added to the current plot.

## References

      t0 = exp.boot$t0)
```

---

logit

*Logit of Proportions*

---

**Description**

This function calculates the logit of proportions.

**Usage**

```
logit(p)
```

**Arguments**

**p** A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

**Details**

If any elements of **p** are outside the unit interval then an error message is generated. Values of **p** equal to 0 or 1 (to within machine precision) will return `-Inf` or `Inf` respectively. Any NAs in the input will also be NAs in the output.

**Value**

A numeric object of the same type as **p** containing the logits of the input values.

**See Also**

[inv.logit](#), [qlogis](#) for which this is a wrapper.

manaus

*Average Heights of the Rio Negro river at Manaus*

## Description

The manaus time series is of class "ts" and has 1080 observations on one variable.

The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

## Source

The data were kindly made available by Professors H. O'Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

melanoma

*Survival from Malignant Melanoma*

## Description

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

**Usage**

```
melanoma
```

**Format**

This data frame contains the following columns:

`time` Survival time in days since the operation, possibly censored.

`status` The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.

`sex` The patients sex; 1=male, 0=female.

`age` Age in years at the time of the operation.

`year` Year of operation.

`thickness` Tumour thickness in mm.

`ulcer` Indicator of ulceration; 1=present, 0=absent.

**Note**

This dataset is not related to the dataset in the **lattice** package with the same name.

**Source**

The data were obtained from

---

motor

*Data from a Simulated Motorcycle Accident*

---

**Description**

The `motor` data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of `time` from the dataset `mcycle`. Two extra columns are added to allow for strata with a different residual variance in each stratum.

**Usage**

```
motor
```

**Format**

This data frame contains the following columns:

`times` The time in milliseconds since impact.

`accel` The recorded head acceleration (in g).

`strata` A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.

`v` An estimate of the residual variance for the observation. `v` is constant within the strata but a different estimate is used for each of the three strata.

**Source**

The data were obtained from

Silverman, B.W. (1985) Some aspects of the spline smoothing approach to non-parametric curve fitting. *Journal of the Royal Statistical Society, B*, **47**, 1–52.

[mcycle](#)

---

neuro

*Neurophysiological Point Process Data*

---

**Description**

`neuro` is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

**Note**

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

**Source**

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

---

nitrofen*Toxicity of Nitrofen in Aquatic Systems*

---

## Description

The `nitrofen` data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

## Usage

```
nitrofen
```

## Format

This data frame contains the following columns:

`conc` The nitrofen concentration in the solution (mug/litre).

`brood1` The number of live offspring in the first brood.

`brood2` The number of live offspring in the second brood.

`brood3` The number of live offspring in the third brood.

`total` The total number of live offspring in the first three broods.

## Source

The data were obtained from

Bailer, A.J. and Oris, J.T. (1994) Assessing toxicity of pollutants in aquatic systems. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 25–40. John Wiley.

nodal

*Nodal Involvement in Prostate Cancer***Description**

The `nodal` data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

**Usage**

```
nodal
```

**Format**

This data frame contains the following columns:

`m` A column of ones.

`r` An indicator of nodal involvement.

`aged` The patients age dichotomized into less than 60 (0) and 60 or over 1.

`stage` A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.

`grade` Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.

`xray` A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.

`acid` The level of acid phosphatase in the blood serum.

**Source**

The data were obtained from

Brown, B.W. (1980) Prediction analysis for binary data. In *Biostatistics Casebook*. R.G. Miller, B. Efron, B.W. Brown and L.E. Moses (editors), 3–18. John Wiley.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

norm.ci

*Normal Approximation Confidence Intervals***Description**

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

**Usage**

```
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
        t0 = NULL, t = NULL, L = NULL, h = function(t) t,
        hdot = function(t) 1, hinv = function(t) t)
```

**Arguments**

<code>boot.out</code>	A bootstrap output object returned from a call to <code>boot</code> . If <code>t0</code> is missing then <code>boot.out</code> is a required argument. It is also required if both <code>var.t0</code> and <code>t</code> are missing.
<code>conf</code>	A scalar or vector containing the confidence level(s) of the required interval(s).
<code>index</code>	The index of the statistic of interest within the output of a call to <code>boot.out\$statistic</code> . It is not used if <code>boot.out</code> is missing, in which case <code>t0</code> must be supplied.
<code>var.t0</code>	The variance of the statistic of interest. If it is not supplied then <code>var(t)</code> is used.
<code>t0</code>	The observed value of the statistic of interest. If it is missing then it is taken from <code>boot.out</code> which is required in that case.
<code>t</code>	Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if <code>var.t0</code> is not supplied. The default value is <code>boot.out\$t[, index]</code> .
<code>L</code>	The empirical influence values for the statistic of interest. These are used to calculate <code>var.t0</code> if neither <code>var.t0</code> nor <code>boot.out</code> are supplied. If a transformation is supplied through <code>h</code> then the influence values must be for the untransformed statistic <code>t0</code> .
<code>h</code>	A function defining a monotonic transformation, the intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> is applied to the resulting intervals. <code>h</code> must be a function of one variable only and must be vectorized. The default is the identity function.
<code>hdot</code>	A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and is used for approximating the variance of <code>h(t0)</code> . The default is the constant function 1.
<code>hinv</code>	A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale.

## Details

It is assumed that the statistic of interest has an approximately normal distribution with variance `var.t0` and so a confidence interval of length  $2 * qnorm((1 + conf) / 2) * sqrt(var.t0)$  is found. If `boot.out` or `t` are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at  $2 * t_0 - mean(t)$ . Otherwise the interval is centred at `t0`.

## Value

If `length(conf)` is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

## Note

This function is primarily designed to be called by `boot.ci` to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as `t0` and `var.t0` can be supplied. See the examples below.

## Examples

```
# In Example 5.1 of Davison and Hinkley (1997), normal approximation
# confidence intervals are found for the air-conditioning data.
air.mean <- mean(aircondit$hours)
air.n <- nrow(aircondit)
air.v <- air.mean^2/air.n
norm.ci(t0 = air.mean, var.t0 = air.v)
exp(norm.ci(t0 = log(air.mean), var.t0 = 1/air.n)[2:3])

# Now a more complicated example - the ratio estimate for the city data.
ratio <- function(d, w)
  sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
norm.ci(t0 = ratio(city, rep(0.1, 10)), var.t0 = city.v)
```

## Description

The `nuclear` data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers' subsidies may be hidden in the quoted capital costs.

## Usage

```
nuclear
```

## Format

This data frame contains the following columns:

`cost` The capital cost of construction in millions of dollars adjusted to 1976 base.

`date` The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.

`t1` The time between application for and issue of the construction permit.

`t2` The time between issue of operating license and construction permit.

`cap` The net capacity of the power plant (MWe).

`pr` A binary variable where 1 indicates the prior existence of a LWR plant at the same site.

`ne` A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.

`ct` A binary variable where 1 indicates the use of a cooling tower in the plant.

`bw` A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.

`cum.n` The cumulative number of power plants constructed by each architect-engineer.

`pt` A binary variable where 1 indicates those plants with partial turnkey guarantees.

## Source

The data were obtained from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

## References

paulsen

*Neurotransmission in Guinea Pig Brains***Description**

The paulsen data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

**Usage**

```
paulsen
```

**Format**

This data frame contains the following column:

y The current flowing into individual brain cells. The currents are measured in pico-amperes.

**Source**

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

Paulsen, O. and Heggelund, P. (1994) The quantal size at retinogeniculate synapses determined from spontaneous and evoked EPSCs in guinea-pig thalamic slices. *Journal of Physiology*, **480**, 505–511.

**References**

plot.boot

*Plots of the Output of a Bootstrap Simulation***Description**

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

**Usage**

```
## S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
     qdist = "norm", nclass = NULL, df, ...)
```

### Arguments

<code>x</code>	An object of class "boot" returned from one of the bootstrap generation functions.
<code>index</code>	The index of the variable of interest within the output of <code>boot.out</code> . This is ignored if <code>t</code> and <code>t0</code> are supplied.
<code>t0</code>	The original value of the statistic. This defaults to <code>boot.out\$t0[index]</code> unless <code>t</code> is supplied when it defaults to <code>NULL</code> . In that case no vertical line is drawn on the histogram.
<code>t</code>	The bootstrap replicates of the statistic. Usually this will take on its default value of <code>boot.out\$t[, index]</code> , however it may be useful sometimes to supply a different set of values which are a function of <code>boot.out\$t</code> .
<code>jack</code>	A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.
<code>qdist</code>	The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.
<code>nclass</code>	An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to <code>ceiling(length(t)/25)</code> .
<code>df</code>	If <code>qdist</code> is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.
<code>...</code>	When <code>jack</code> is TRUE additional parameters to <code>jack.after.boot</code> can be supplied. See the help file for <code>jack.after.boot</code> for details of the possible parameters.

### Details

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot be done if `t` is supplied but `t0` is not and so, in that case, the breakpoints are computed by `hist` using the `nclass` argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept `mean(t)` and slope `sqrt(var(t))` while for the chi-squared it has intercept 0 and slope 1.

If `jack` is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See `jack.after.boot` for further details of this plot.

### Value

`boot.out` is returned invisibly.

### Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

poisons

*Animal Survival Times*

---

### Description

The `poisons` data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

### Usage

```
poisons
```

### Format

This data frame contains the following columns:

`time` The survival time of the animal in units of 10 hours.

`poison` A factor with levels 1, 2 and 3 giving the type of poison used.

`treat` A factor with levels A, B, C and D giving the treatment.

### Source

The data were obtained from

Box, G.E.P. and Cox, D.R. (1964) An analysis of transformations (with Discussion). *Journal of the Royal Statistical Society, B*, **26**, 211–252.

polar

*Pole Positions of New Caledonian Laterites*

---

### Description

The `polar` data frame has 50 rows and 2 columns.

The data are the pole positions from a paleomagnetic study of New Caledonian laterites.

### Usage

```
polar
```

**Format**

This data frame contains the following columns:

- lat The latitude (in degrees) of the pole position. Note that all latitudes are negative as the axis is taken to be in the lower hemisphere.
- long The longitude (in degrees) of the pole position.

**Source**

The data were obtained from

Fisher, N.I., Lewis, T. and Embleton, B.J.J. (1987) *Statistical Analysis of Spherical Data*. Cambridge University Press.

---

print.boot	<i>Print a Summary of a Bootstrap Object</i>
------------	--

---

**Description**

This is a method for the function `print()` for objects of the class "boot".

**Usage**

```
## S3 method for class 'boot'
print(x, digits = getOption("digits"),
      index = 1:ncol(boot.out$t), ...)
```

**Arguments**

- x A bootstrap output object of class "boot" generated by one of the bootstrap functions.
- digits The number of digits to be printed in the summary statistics.
- index Indices indicating for which elements of the bootstrap output summary statistics are required.
- ... further arguments passed to or from other methods.

**Details**

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t=FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

**Value**

The bootstrap object is returned invisibly.

**See Also**

[boot](#), [censboot](#), [imp.moments](#), [plot.boot](#), [tilt.boot](#), [tsboot](#)

---

print.bootci

*Print Bootstrap Confidence Intervals*

---

**Description**

This is a method for the function `print()` to print objects of the class "bootci".

**Usage**

```
## S3 method for class 'bootci'
print(x, hinv = NULL, ...)
```

**Arguments**

<code>x</code>	The output from a call to <code>boot.ci</code> .
<code>hinv</code>	A transformation to be made to the interval end-points before they are printed.
<code>...</code>	further arguments passed to or from other methods.

**Details**

This function prints out the results from `boot.ci` in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to `boot.ci` or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

```
Warning : Intervals used Extreme Quantiles
```

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

```
Some intervals may be unstable
```

**Value**

The object `ci.out` is returned invisibly.

**See Also**

[boot.ci](#)

---

print.saddle.distn *Print Quantiles of Saddlepoint Approximations*

---

### Description

This is a method for the function `print()` to print objects of class `"saddle.distn"`.

### Usage

```
## S3 method for class 'saddle.distn'  
print(x, ...)
```

### Arguments

x	An object of class <code>"saddle.distn"</code> created by a call to <code>saddle.distn</code> .
...	further arguments passed to or from other methods.

### Details

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

### Value

The input is returned invisibly.

### See Also

[lines.saddle.distn](#), [saddle.distn](#)

---

print.simplex *Print Solution to Linear Programming Problem*

---

### Description

This is a method for the function `print()` to print objects of class `"simplex"`.

### Usage

```
## S3 method for class 'simplex'  
print(x, ...)
```

### Arguments

x	An object of class <code>"simplex"</code> created by calling the function <code>simplex</code> to solve a linear programming problem.
...	further arguments passed to or from other methods.

**Details**

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

**Value**

`x` is returned silently.

**See Also**

[simplex](#)

---

remission	<i>Cancer Remission and Cell Activity</i>
-----------	---

---

**Description**

The `remission` data frame has 27 rows and 3 columns.

**Usage**

```
remission
```

**Format**

This data frame contains the following columns:

- `LI` A measure of cell activity.
- `m` The number of patients in each group (all values are actually 1 here).
- `r` The number of patients (out of `m`) who went into remission.

**Source**

The data were obtained from  
Freeman, D.H. (1987) *Applied Categorical Data Analysis*. Marcel Dekker.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**Description**

This function calculates a saddlepoint approximation to the distribution of a linear combination of  $\mathbf{W}$  at a particular point  $u$ , where  $\mathbf{W}$  is a vector of random variables. The distribution of  $\mathbf{W}$  may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of  $\mathbf{W}$  can be calculated for  $\mathbf{W}$  having binary or Poisson distributions.

**Usage**

```
saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL,
       d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
       strata = NULL, K.adj = NULL, K2 = NULL)
```

**Arguments**

<code>A</code>	A vector or matrix of known coefficients of the linear combinations of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.
<code>u</code>	The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.
<code>wdist</code>	The distribution of $\mathbf{W}$ . This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If <code>K.adj</code> and <code>K2</code> are given <code>wdist</code> is set to "o".
<code>type</code>	The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When <code>wdist</code> is "o" or "m", <code>type</code> is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.
<code>d</code>	This specifies the dimension of the whole statistic. This argument is required only when <code>wdist</code> = "o" and defaults to 1 if not supplied in that case. For other distributions it is set to <code>ncol(A)</code> .
<code>d1</code>	When <code>type</code> is "cond" this is the dimension of the statistic of interest which must be less than <code>length(u)</code> . Then the saddlepoint approximation to the conditional distribution of the first <code>d1</code> linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of <code>d1</code> is 1.
<code>init</code>	Used if <code>wdist</code> is either "m" or "o", this gives initial values to <code>nlmin</code> which is used to solve the saddlepoint equation.
<code>mu</code>	The values of the parameters of the distribution of $\mathbf{W}$ when <code>wdist</code> is "m", "p" or "b". <code>mu</code> must be of the same length as $\mathbf{W}$ (i.e. <code>nrow(A)</code> ). The default is that all values of <code>mu</code> are equal and so the elements of $\mathbf{W}$ are identically distributed.
<code>LR</code>	If TRUE then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's $r^*$ .
<code>strata</code>	The strata for stratified data.

<code>K.adj</code>	The adjusted cumulant generating function used when <code>wdist</code> is "o". This is a function of a single parameter, <code>zeta</code> , which calculates $K(zeta) - u * zeta$ , where $K(zeta)$ is the cumulant generating function of $W$ .
<code>K2</code>	This is a function of a single parameter <code>zeta</code> which returns the matrix of second derivatives of $K(zeta)$ for use when <code>wdist</code> is "o". If <code>K.adj</code> is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if <code>K.adj</code> is not supplied.

### Details

If `wdist` is "o" or "m", the saddlepoint equations are solved using `nlmin` to minimize `K.adj` with respect to its parameter `zeta`. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the `glm` must satisfy the equation  $t(A) \%*\%y = u(t())$  being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to `simplex`. The covariate matrix for the `glm` is given by `A`.

### Value

A list consisting of the following components

<code>spa</code>	The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.
<code>zeta.hat</code>	The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.
<code>zeta2.hat</code>	If <code>type</code> is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of <code>type</code> .

### Examples

```
# To evaluate the bootstrap distribution of the mean failure time of
# air-conditioning equipment at 80 hours
saddle(A = aircondit$hours/12, u = 80)

# Alternatively this can be done using a conditional poisson
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
```

```

wdist = "p", type = "cond")

# To use the Lugananni-Rice approximation to this
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
       wdist = "p", type = "cond",
       LR = TRUE)

# Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
# approximations to the distribution of the ratio statistic for the
# city data. Since the statistic is not in itself a linear combination
# of random Variables, its distribution cannot be found directly.
# Instead the statistic is expressed as the solution to a linear
# estimating equation and hence its distribution can be found. We
# get the saddlepoint approximation to the pdf and cdf evaluated at
# t = 1.25 as follows.
jacobian <- function(dat,t,zeta)
{
  p <- exp(zeta*(dat$x-t*dat$u))
  abs(sum(dat$u*p)/sum(p))
}
city.sp1 <- saddle(A = city$x-1.25*city$u, u = 0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1

```

saddle.distn

*Saddlepoint Distribution Approximations for Bootstrap Statistics*

## Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of  $\mathbf{W}$  where  $\mathbf{W}$  is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of  $\mathbf{W}$  must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function [control](#) to approximate the distribution of the linear approximation to a statistic.

## Usage

```

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m",
             type = "simp", npts = 20, t = NULL, t0 = NULL,
             init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
             strata = NULL, ...)

```

## Arguments

**A** This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point  $t$  at which a saddlepoint is required. The most common reason for  $A$  being a function would be if the statistic is not itself a linear combination of the  $\mathbf{W}$  but is the solution to a linear estimating equation.

<code>u</code>	If <code>A</code> is a function then <code>u</code> must also be a function returning a vector with length equal to the number of columns of the matrix returned by <code>A</code> . Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If <code>A</code> is a matrix with more than one column (such as when <code>wdist = "cond"</code> ) then <code>u</code> should be a vector with length one less than <code>ncol(A)</code> . In this case <code>u</code> specifies the values of the conditioning variables. If <code>A</code> is a matrix with one column or a vector then <code>u</code> is not used.
<code>alpha</code>	The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.
<code>wdist</code>	The distribution of <b>W</b> . Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).
<code>type</code>	The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If <code>wdist</code> is "m", <code>type</code> is set to "simp".
<code>npts</code>	The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.
<code>t</code>	A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in <code>t</code> as the distribution function approximation breaks down at that point. The points should, however cover the entire effective range of the distribution including close to the centre. If <code>t</code> is supplied then <code>npts</code> is set to <code>length(t)</code> . When <code>t</code> is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range.
<code>t0</code>	If <code>t</code> is not supplied then a vector of length 2 should be passed as <code>t0</code> . The first component of <code>t0</code> should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in <code>t0[1]</code> .
<code>init</code>	When <code>wdist</code> is "m", this vector should contain the initial values to be passed to <code>nlmin</code> when it is called to solve the saddlepoint equations.
<code>mu</code>	The vector of parameter values for the distribution. The default is that the components of <b>W</b> are identically distributed.
<code>LR</code>	A logical flag. When <code>LR</code> is <code>TRUE</code> the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen's $r^*$ .
<code>strata</code>	A vector giving the strata when the rows of <code>A</code> relate to stratified data. This is used only when <code>wdist</code> is "m".
<code>...</code>	When <code>A</code> and <code>u</code> are functions any additional arguments are passed unchanged each time one of them is called.

## Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of `alpha`. The lower endpoint is found by evaluating the saddlepoint at the points `t0[1]-2*t0[2]`, `t0[1]-4*t0[2]`, `t0[1]-8*t0[2]` etc. until a point is found with a cdf approximation less than `min(alpha)/10`, then a bisection method is used to find the endpoint which has cdf approximation in the range `(min(alpha)/1000, min(alpha)/10)`. Then a number of, equally spaced, points are chosen

between the lower endpoint and `t0[1]` until a total of `npts/2` approximations have been made. The remaining `npts/2` points are chosen to the right of `t0[1]` in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of `t0[2]` is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of `t0[2]` will usually solve the problem.

### Value

The returned value is an object of class "saddle.distn". See the help file for [saddle.distn.object](#) for a description of such an object.

---

saddle.distn.object

*Saddlepoint Distribution Approximation Objects*

---

## Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

## Generation

This class of objects is returned from calls to the function `saddle.distn`.

## Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

## Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

**quantiles** A matrix with 2 columns. The first column contains the probabilities  $\alpha$  and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

**points** A matrix of evaluations of the saddlepoint approximation. The first column contains the values of  $t$  which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When `type` is "simp", there is only one of those. When `type` is "cond" there are  $2*d-1$  where  $d$  is the number of columns in  $A$  or the output of  $A(t, \dots)$ . The first  $d$  of these correspond to the numerator and the remainder correspond to the denominator.

**distn** An object of class `smooth.spline`. This corresponds to the spline fitted to the saddlepoint cdf approximations in points in order to approximate the entire distribution. For the structure of the object see `smooth.spline`.

**call** The original call to `saddle.distn` which generated the object.

**LR** A logical variable indicating whether the Lugananni-Rice approximations were used.

salinity

*Water Salinity and River Discharge***Description**

The `salinity` data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

```
salinity
```

**Format**

This data frame contains the following columns:

`sal` The average salinity of the water over two weeks.

`lag` The average salinity of the water lagged two weeks. Since only spring is used, the value of `lag` is not always equal to the previous value of `sal`.

`trend` A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

`dis` The amount of river discharge during the two weeks for which `sal` is the average salinity.

**Source**

The data were obtained from

Ruppert, D. and Carroll, R.J. (1980) Trimmed least squares estimation in the linear model. *Journal of the American Statistical Association*, **75**, 828–838.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

simplex

*Simplex Method for Linear Programming Problems***Description**

This function will optimize the linear function  $a \% \% x$  subject to the constraints  $A1 \% \% x \leq b1$ ,  $A2 \% \% x \geq b2$ ,  $A3 \% \% x = b3$  and  $x \geq 0$ . Either maximization or minimization is possible but the default is minimization.

**Usage**

```
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
       b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

**Arguments**

<code>a</code>	A vector of length <code>n</code> which gives the coefficients of the objective function.
<code>A1</code>	An <code>m1</code> by <code>n</code> matrix of coefficients for the $\leq$ type of constraints.
<code>b1</code>	A vector of length <code>m1</code> giving the right hand side of the $\leq$ constraints. This argument is required if <code>A1</code> is given and ignored otherwise. All values in <code>b1</code> must be non-negative.
<code>A2</code>	An <code>m2</code> by <code>n</code> matrix of coefficients for the $\geq$ type of constraints.
<code>b2</code>	A vector of length <code>m2</code> giving the right hand side of the $\geq$ constraints. This argument is required if <code>A2</code> is given and ignored otherwise. All values in <code>b2</code> must be non-negative. Note that the constraints $x \geq 0$ are included automatically and so should not be repeated here.
<code>A3</code>	An <code>m3</code> by <code>n</code> matrix of coefficients for the equality constraints.
<code>b3</code>	A vector of length <code>m3</code> giving the right hand side of equality constraints. This argument is required if <code>A3</code> is given and ignored otherwise. All values in <code>b3</code> must be non-negative.
<code>maxi</code>	A logical flag which specifies minimization if <code>FALSE</code> (default) and maximization otherwise. If <code>maxi</code> is <code>TRUE</code> then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.
<code>n.iter</code>	The maximum number of iterations to be conducted in each phase of the simplex method. The default is <code>n+2*(m1+m2+m3)</code> .
<code>eps</code>	The floating point tolerance to be used in tests of equality.

**Details**

The method employed by this function is the two phase tableau simplex method. If there are  $\geq$  or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each  $\geq$  or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the  $\leq$  form, the origin is a feasible solution and so the first stage can be omitted.

**Value**

An object of class "simplex": see `simplex.object`.

**Note**

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form  $x[i] \geq b2[i]$  they should be omitted by setting  $x[i] = x[i] - b2[i]$ , changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

fat <- c(800, 6000, 1000, 400)
vitx <- c(50, 3, 150, 100)
vity <- c(10, 10, 75, 100)
vitz <- c(150, 35, 75, 5)
simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
       b2 = c(600, 300, 550), maxi = TRUE)
```

---

simplex.object

*Linear Programming Solution Objects*

---

## Description

Class of objects that result from solving a linear programming problem using `simplex`.

## Generation

This class of objects is returned from calls to the function `simplex`.

## Methods

The class `"saddle.distn"` has a method for the function `print`.

## Structure

Objects of class `"simplex"` are implemented as a list with the following components.

**soln** The values of  $x$  which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

**solved** This indicates whether the problem was solved. A value of  $-1$  indicates that no feasible solution could be found. A value of  $0$  that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of  $1$  indicates that an optimal solution has been found.

**value** The value of the objective function at `soln`.

**val.aux** This is `NULL` if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

**obj** The original coefficients of the objective function.

**a** The objective function coefficients re-expressed such that the basic variables have coefficient zero.

**a.aux** This is `NULL` if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.

**A** The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions  $m_1+m_2+m_3$  by  $n+m_1+m_2$ , where the final  $m_1+m_2$  columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional  $m_1+m_2+m_3$  columns for the artificial variables introduced to solve the first phase of the problem.

**basic** The indices of the basic (non-zero) variables in the solution. Indices between  $n+1$  and  $n+m_1$  correspond to slack variables, those between  $n+m_1+1$  and  $n+m_2$  correspond to surplus variables and those greater than  $n+m_2$  are artificial variables. Indices greater than  $n+m_2$  should occur only if `solved` is `-1` as the artificial variables are discarded in the second stage of the simplex method.

**slack** The final values of the  $m_1$  slack variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A1\%*x + \text{slack} = b1$ .

**surplus** The final values of the  $m_2$  surplus variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A2\%*x - \text{surplus} = b2$ .

**artificial** This is `NULL` if a feasible solution can be found. If no solution can be found then this contains the values of the  $m_1+m_2+m_3$  artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

---

smooth.f

*Smooth Distributions on Data Points*

---

### Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, `theta`, of the statistic of interest. The method results in distributions which vary smoothly with `theta`.

### Usage

```
smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index],
         width = 0.5)
```

### Arguments

<code>theta</code>	The required value for the statistic of interest. If <code>theta</code> is a vector, a separate distribution will be found for each element of <code>theta</code> .
<code>boot.out</code>	A bootstrap output object returned by a call to <code>boot</code> .
<code>index</code>	The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This argument is ignored if <code>t</code> is supplied. <code>index</code> must be a scalar.
<code>t</code>	The bootstrap values of the statistic of interest. This must be a vector of length <code>boot.out\$R</code> and the values must be in the same order as the bootstrap replicates in <code>boot.out</code> .
<code>width</code>	The standardized width for the kernel smoothing. The smoothing uses a value of <code>width*s</code> for epsilon, where <code>s</code> is the bootstrap estimate of the standard error of the statistic of interest. <code>width</code> should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If <code>width</code> is too large then the distribution becomes closer to uniform.

## Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of  $\tau$  weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value `theta` but it will typically have a value which is close to `theta`. The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

## Value

If `length(theta)` is 1 then a vector with the same length as the data set `boot.out$data` is returned. The value in position `i` is the probability to be given to the data point in position `i` so that the distribution has parameter value approximately equal to `theta`. If `length(theta)` is bigger than 1 then the returned value is a matrix with `length(theta)` rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of `theta`.

## Examples

```
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. In the book exponential tilting was used
# but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum(mn2 - mns^2)/ns
  c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1],
  weights = grav.sm)

# Estimated p-values can be found from these as follows
```

```

mean(grav.boot$t[, 3] >= grav.z0[3])
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
# can give very strange results (negative probabilities).

```

sunspot

*Annual Mean Sunspot Numbers*

---

### Description

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by  $k(f+10g)$  where  $g$  is the number of sunspot groups observed,  $f$  is the total number of spots within the groups and  $k$  is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

survival

*Survival of Rats after Radiation Doses*

---

### Description

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

**Usage**

```
survival
```

**Format**

This data frame contains the following columns:

dose The dose of radiation administered (rads).

surv The survival rate of the batches expressed as a percentage.

**Source**

The data were obtained from

tau	<i>Tau Particle Decay Modes</i>
-----	---------------------------------

---

**Description**

The tau data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970's by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

**Usage**

```
tau
```

**Format**

This data frame contains the following columns:

rate The decay rate expressed as a percentage.

decay The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

Source

The data were obtained from

---

tilt.boot	<i>Non-parametric Tilted Bootstrap</i>
-----------	--

---

Description

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

Usage

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i",
          strata = rep(1, n), L = NULL, theta = NULL,
          alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5,
          index = 1, ...)
```

Arguments

data	The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.
statistic	A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be data and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to tilt.boot and will be passed unchanged to statistic each time it is called.
R	The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of R are the number of simulations to be performed resampling from each reweighted distribution. The first value of R must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus length(R) should always equal 1+length(theta).
sim	This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.

stype	A character string indicating the type of second argument expected by <code>statistic</code> . The possible values that <code>stype</code> can take are "i" (indices), "w" (weights) and "f" (frequencies).
strata	An integer vector or factor representing the strata for multi-sample problems.
L	The empirical influence values for the statistic of interest. They are used only for exponential tilting when <code>tilt</code> is TRUE. If <code>tilt</code> is TRUE and they are not supplied then <code>tilt.boot</code> uses <code>empinf</code> to calculate them.
theta	The required parameter value(s) for the tilted distribution(s). There should be one value of <code>theta</code> for each of the non-uniform distributions. If <code>R[1]</code> is 0 <code>theta</code> is a required argument. Otherwise <code>theta</code> values can be estimated from the initial uniform bootstrap and the values in <code>alpha</code> .
alpha	The alpha level to which tilting is required. This parameter is ignored if <code>R[1]</code> is 0 or if <code>theta</code> is supplied, otherwise it is used to find the values of <code>theta</code> as quantiles of the initial uniform bootstrap. In this case <code>R[1]</code> should be large enough that $\min(c(\alpha, 1-\alpha)) * R[1] > 5$ , if this is not the case then a warning is generated to the effect that the <code>theta</code> are extreme values and so the tilted output may be unreliable.
tilt	A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing ( <code>smooth.f</code> ) is used. If <code>tilt</code> is FALSE then <code>R[1]</code> must be positive. In fact in this case the value of <code>R[1]</code> should be fairly large (in the region of 500 or more).
width	This argument is used only if <code>tilt</code> is FALSE, in which case it is passed unchanged to <code>smooth.f</code> as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See <code>smooth.f</code> for more details.
index	The index of the statistic of interest in the output from <code>statistic</code> . By default the first element of the output of <code>statistic</code> is used.
...	Any additional arguments required by <code>statistic</code> . These are passed unchanged to <code>statistic</code> each time it is called.

## Value

An object of class "boot" with the following components

t0	The observed value of the statistic on the original data.
t	The values of the bootstrap replicates of the statistic. There will be <code>sum(R)</code> of these, the first <code>R[1]</code> corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).
R	The input vector of the number of bootstrap replicates.
data	The original data as supplied.
statistic	The <code>statistic</code> function as supplied.
sim	The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".
stype	The type of statistic supplied, it is the same as the input value <code>stype</code> .
call	A copy of the original call to <code>tilt.boot</code> .
strata	The strata as supplied.
weights	The matrix of weights used. If <code>R[1]</code> is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If <code>R[1]</code> equals 0 then the uniform weights are omitted and only the tilted weights are output.

`theta` The values of `theta` used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and `alpha`.

  sr <- sqrt(sum(tmp^2))/SSx
  c(beta.b, sr, (beta.b-bhat)/sr)
}
acme.b <- acme.fun(acme, 1:nrow(acme), 0)
acme.boot1 <- tilt.boot(acme, acme.fun, R = c(499, 250, 250),
                      stype = "i", sim = "balanced", alpha = c(0.05, 0.95),
                      tilt = TRUE, index = 3, bhat = acme.b[1])
```

**Description**

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

**Usage**

```
tsboot(tseries, statistic, R, l = NULL, sim = "model",
       endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE,
       ran.gen, ran.args = NULL, norm = TRUE, ...,
       parallel = c("no", "multicore", "snow"),
       ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

<code>tseries</code>	A univariate or multivariate time series.
<code>statistic</code>	A function which when applied to <code>tseries</code> returns a vector containing the statistic(s) of interest. Each time <code>statistic</code> is called it is passed a time series of length <code>n.sim</code> which is of the same class as the original <code>tseries</code> . Any other arguments which <code>statistic</code> takes must remain constant for each bootstrap replicate and should be supplied through the <code>...</code> argument to <code>tsboot</code> .
<code>R</code>	A positive integer giving the number of bootstrap replicates required.
<code>sim</code>	The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of 1), "geom" (block resampling with block lengths having a geometric distribution with mean 1) or "scramble" (phase scrambling).
<code>l</code>	If <code>sim</code> is "fixed" then <code>l</code> is the fixed block length used in generating the replicate time series. If <code>sim</code> is "geom" then <code>l</code> is the mean of the geometric distribution used to generate the block lengths. <code>l</code> should be a positive integer less than the length of <code>tseries</code> . This argument is not required when <code>sim</code> is "model" but it is required for all other simulation types.
<code>endcorr</code>	A logical variable indicating whether end corrections are to be applied when <code>sim</code> is "fixed". When <code>sim</code> is "geom", <code>endcorr</code> is automatically set to TRUE; <code>endcorr</code> is not used when <code>sim</code> is "model" or "scramble".
<code>n.sim</code>	The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which <code>n.sim</code> is larger than the original length is if <code>tseries</code> is a residual time series from fitting some model to the original time series. In this case, <code>n.sim</code> would usually be the length of the original time series.
<code>orig.t</code>	A logical variable which indicates whether <code>statistic</code> should be applied to <code>tseries</code> itself as well as the bootstrap replicate series. If <code>statistic</code> is expecting a longer time series than <code>tseries</code> or if applying <code>statistic</code> to <code>tseries</code> will not yield any useful information then <code>orig.t</code> should be set to FALSE.

<code>ran.gen</code>	This is a function of three arguments. The first argument is a time series. If <code>sim</code> is "model" then it will always be <code>tseries</code> that is passed. For other simulation types it is the result of selecting <code>n.sim</code> observations from <code>tseries</code> by some scheme and converting the result back into a time series of the same form as <code>tseries</code> (although of length <code>n.sim</code> ). The second argument to <code>ran.gen</code> is always the value <code>n.sim</code> , and the third argument is <code>ran.args</code> , which is used to supply any other objects needed by <code>ran.gen</code> . If <code>sim</code> is "model" then the generation of the replicate time series will be done in <code>ran.gen</code> (for example through use of <code>arima.sim</code> ). For the other simulation types <code>ran.gen</code> is used for 'post-blackening'. The default is that the function simply returns the time series passed to it.
<code>ran.args</code>	This will be supplied to <code>ran.gen</code> each time it is called. If <code>ran.gen</code> needs any extra arguments then they should be supplied as components of <code>ran.args</code> . Multiple arguments may be passed by making <code>ran.args</code> a list. If <code>ran.args</code> is <code>NULL</code> then it should not be used within <code>ran.gen</code> but note that <code>ran.gen</code> must still have its third argument.
<code>norm</code>	A logical argument indicating whether normal margins should be used for phase scrambling. If <code>norm</code> is <code>FALSE</code> then margins corresponding to the exact empirical margins are used.
<code>...</code>	Extra named arguments to <code>statistic</code> may be supplied here. Beware of partial matching to the arguments of <code>tsboot</code> listed above.
<code>parallel, ncpus, cl</code>	See the help for <code>boot</code> .

## Details

If `sim` is "fixed" then each replicate time series is found by taking blocks of length `l`, from the original time series and putting them end-to-end until a new series of length `n.sim` is created. When `sim` is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean 1. Post-blackening can be carried out on these replicate time series by including the function `ran.gen` in the call to `tsboot` and having `tseries` as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function `boot` with the argument `sim = "parametric"`.

## Value

An object of class "boot" with the following components.

<code>t0</code>	If <code>orig.t</code> is <code>TRUE</code> then <code>t0</code> is the result of <code>statistic(tseries, ...)</code> otherwise it is <code>NULL</code> .
<code>t</code>	The results of applying <code>statistic</code> to the replicate time series.
<code>R</code>	The value of <code>R</code> as supplied to <code>tsboot</code> .
<code>tseries</code>	The original time series.
<code>statistic</code>	The function <code>statistic</code> as supplied.

<code>sim</code>	The simulation type used in generating the replicates.
<code>endcorr</code>	The value of <code>endcorr</code> used. The value is meaningful only when <code>sim</code> is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if <code>sim</code> is "geom".
<code>n.sim</code>	The value of <code>n.sim</code> used.
<code>l</code>	The value of <code>l</code> used for block based resampling. This will be NULL if block based resampling was not used.
<code>ran.gen</code>	The <code>ran.gen</code> function used for generating the series or for 'post-blackening'.
<code>ran.args</code>	The extra arguments passed to <code>ran.gen</code> .
<code>call</code>	The original call to <code>tsboot</code> .

## Examples

```
lynx.fun <- function(tsb) {
  ar.fit <- ar(tsb, order.max = 25)
  c(ar.fit$order, mean(tsb), tsb)
}

# the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "geom")

# the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "fixed")

# Now for model based resampling we need the original model
# Note that for all of the bootstraps which use the residuals as their
# data, we set orig.t to FALSE since the function applied to the residual
# time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order = c(lynx.ar$order, 0, 0), ar = lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res, n.sim, ran.args) {
  # random generation of replicate series using arima.sim
  rgl <- function(n, res) sample(res, n, replace = TRUE)
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim,
    rand.gen = rgl, res = as.vector(res)))
}
```

```

}

lynx.3 <- tsboot(lynx.res, lynx.fun, R = 99, sim = "model", n.sim = 114,
               orig.t = FALSE, ran.gen = lynx.sim,
               ran.args = list(ts = log(lynx), model = lynx.model))

# For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args) {
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, innov = res))
}

# Now we can run apply the two types of block resampling again but this
# time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "fixed",
                 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
                 ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom",
                 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
                 ran.args = list(ts = log(lynx), model = lynx.model))

# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])
# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.

```

tuna

### *Tuna Sighting Data*

---

## Description

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

## Usage

```
tuna
```

## Format

This data frame contains the following column:

- y The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.

**Source**

The data were obtained from

Chen, S.X. (1996) Empirical likelihood confidence intervals for nonparametric density estimation. *Biometrika*, **83**, 329–341.

---

urine

*Urine Analysis Data*

---

**Description**

The `urine` data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

**Usage**

`urine`

**Format**

This data frame contains the following columns:

`r` Indicator of the presence of calcium oxalate crystals.

`gravity` The specific gravity of the urine.

`ph` The pH reading of the urine.

`osmo` The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.

`cond` The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.

`urea` The urea concentration in millimoles per litre.

`calc` The calcium concentration in millimoles per litre.

**Source**

The data were obtained from

Andrews, D.F. and Herzberg, A.M. (1985) *Data: A Collection of Problems from Many Fields for the Student and Research Worker*. Springer-Verlag.

<code>var.linear</code>	<i>Linear Variance Estimate</i>
-------------------------	---------------------------------

---

**Description**

Estimates the variance of a statistic from its empirical influence values.

**Usage**

```
var.linear(L, strata = NULL)
```

**Arguments**

<code>L</code>	Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> .
<code>strata</code>	A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.

**Value**

The variance estimate calculated from `L`.

**References**

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**See Also**

**Examples**

```
# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w) sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data = city, statistic = ratio))
```

---

<code>wool</code>	<i>Australian Relative Wool Prices</i>
-------------------	--

---

**Description**

`wool` is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

### Source

The data were obtained from

Diggle, P.J. (1990) *Time Series: A Biostatistical Introduction*. Oxford University Press.

## Chapter 19

# The `class` package

---

`batchSOM`

*Self-Organizing Maps: Batch Algorithm*

---

### Description

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

### Usage

```
batchSOM(data, grid = somgrid(), radii, init)
```

### Arguments

<code>data</code>	a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
<code>grid</code>	A grid for the representatives: see <a href="#">somgrid</a> .
<code>radii</code>	the radii of the neighbourhood to be used for each pass: one pass is run for each element of <code>radii</code> .
<code>init</code>	the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .

### Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

### Value

An object of class "`SOM`" with components

<code>grid</code>	the grid, an object of class " <code>somgrid</code> ".
<code>codes</code>	a matrix of representatives.

---

condense	<i>Condense training set for k-NN classifier</i>
----------	--

---

Description

Condense training set for k-NN classifier

Usage

```
condense(train, class, store, trace = TRUE)
```

Arguments

train	matrix for training set
class	vector of classifications for test set
store	initial store set. Default one randomly chosen element of the set.
trace	logical. Trace iterations?

Details

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

Value

Index vector of cases to be retained (the final store set).

```

---

knn	<i>k-Nearest Neighbour Classification</i>
-----	---

---

Description

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

Usage

```
knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

Arguments

<code>train</code>	matrix or data frame of training set cases.
<code>test</code>	matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
<code>cl</code>	factor of true classifications of training set
<code>k</code>	number of neighbours considered.
<code>l</code>	minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than <code>k-1</code> dissenting votes are allowed, even if <code>k</code> is increased by ties.)
<code>prob</code>	If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .
<code>use.all</code>	controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly <code>k</code> neighbours.

**Value**

Factor of classifications of test set. `doubt` will be returned as NA.

**References**

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.

attributes(.Last.value)
```

---

knn.cv

*k-Nearest Neighbour Cross-Validatory Classification*

---

**Description**

k-nearest neighbour cross-validatory classification from training set.

**Usage**

```
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

**Arguments**

<code>train</code>	matrix or data frame of training set cases.
<code>cl</code>	factor of true classifications of training set
<code>k</code>	number of neighbours considered.
<code>l</code>	minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than $k-1$ dissenting votes are allowed, even if $k$ is increased by ties.)
<code>prob</code>	If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .
<code>use.all</code>	controls handling of ties. If true, all distances equal to the $k$ th largest are included. If false, a random selection of distances equal to the $k$ th is chosen to use exactly $k$ neighbours.

**Details**

This uses leave-one-out cross validation. For each row of the training set `train`, the  $k$  nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the  $k$ th nearest vector, all candidates are included in the vote.

**Value**

Factor of classifications of training set. `doubt` will be returned as NA.

---

knn1

---

*1-Nearest Neighbour Classification*

---

**Description**

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

**Usage**

```
knn1(train, test, cl)
```

**Arguments**

<code>train</code>	matrix or data frame of training set cases.
<code>test</code>	matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
<code>cl</code>	factor of true classification of training set.

**Value**

Factor of classifications of test set.

*Learning Vector Quantization I***Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

**Arguments**

<code>x</code>	a matrix or data frame of examples
<code>cl</code>	a vector or factor of classifications for the examples
<code>codebk</code>	a codebook
<code>niter</code>	number of iterations
<code>alpha</code>	constant for training

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

```

---

lvq3

*Learning Vector Quantization 3*

---

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
     win = 0.3, epsilon = 0.1)
```

**Arguments**

<code>x</code>	a matrix or data frame of examples
<code>cl</code>	a vector or factor of classifications for the examples
<code>codebk</code>	a codebook
<code>niter</code>	number of iterations
<code>alpha</code>	constant for training
<code>win</code>	a tolerance for the closeness of the two nearest vectors.
<code>epsilon</code>	proportion of move for correct vectors

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

lvqinit	<i>Initialize a LVQ Codebook</i>
---------	----------------------------------

---

Description

Construct an initial codebook for LVQ methods.

Usage

```
lvqinit(x, cl, size, prior, k = 5)
```

Arguments

x	a matrix or data frame of training examples, n by p.
cl	the classifications for the training examples. A vector or factor of length n.
size	the size of the codebook. Defaults to <code>min(round(0.4*ng*(ng-1 + p/2), 0), n)</code> where ng is the number of classes.
prior	Probabilities to represent classes in the codebook. Default proportions in the training set.
k	k used for k-NN test of correct classification. Default is 5.

Details

Selects `size` examples from the training set without replacement with proportions proportional to the prior or the original proportions.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

lvqtest	<i>Classify Test Set from LVQ Codebook</i>
---------	--

---

Description

Classify a test set by 1-NN from a specified LVQ codebook.

Usage

```
lvqtest(codebk, test)
```

Arguments

codebk	codebook object returned by other LVQ software
test	matrix of test examples

Details

Uses 1-NN to classify each test example against the codebook.

Value

Factor of classification for each row of `x`

---

**Description**

Multiedit for k-NN classifier

**Usage**

```
multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)
```

**Arguments**

x	matrix of training set.
class	vector of classification of training set.
k	number of neighbours used in k-NN.
V	divide training set into V parts.
I	number of null passes before quitting.
trace	logical for statistics at each pass.

**Value**

Index vector of cases to be retained.

reduce.nn

*Reduce Training Set for a k-NN Classifier*

---

**Description**

Reduce training set for a k-NN classifier. Used after `condense`.

**Usage**

```
reduce.nn(train, ind, class)
```

**Arguments**

<code>train</code>	matrix for training set
<code>ind</code>	Initial list of members of the training set (from <code>condense</code> ).
<code>class</code>	vector of classifications for test set

**Details**

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

**Value**

Index vector of cases to be retained.

SOM

*Self-Organizing Maps: Online Algorithm***Description**

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

**Usage**

```
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

**Arguments**

<code>data</code>	a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
<code>grid</code>	A grid for the representatives: see <a href="#">somgrid</a> .
<code>rlen</code>	the number of updates: used only in the defaults for <code>alpha</code> and <code>radii</code> .
<code>alpha</code>	the amount of change: one update is done for each element of <code>alpha</code> . Default is to decline linearly from 0.05 to 0 over <code>rlen</code> updates.
<code>radii</code>	the radii of the neighbourhood to be used for each update: must be the same length as <code>alpha</code> . Default is to decline linearly from 4 to 1 over <code>rlen</code> updates.
<code>init</code>	the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .

**Details**

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

**Value**

An object of class "SOM" with components

<code>grid</code>	the grid, an object of class "somgrid".
<code>codes</code>	a matrix of representatives.

## Examples

```
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

## 2-phase training
crabs.som2 <- SOM(lcrabs, gr,
  alpha = list(seq(0.05, 0, len = 1e4), seq(0.02, 0, len = 1e5)),
  radii = list(seq(8, 1, len = 1e4), seq(4, 1, len = 1e5)))
plot(crabs.som2)
```

---

somgrid

*Plot SOM Fits*

---

## Description

Plotting functions for SOM results.

## Usage

```
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

## S3 method for class 'somgrid'
plot(x, type = "p", ...)

## S3 method for class 'SOM'
plot(x, ...)
```

## Arguments

<code>xdim, ydim</code>	dimensions of the grid
<code>topo</code>	the topology of the grid.
<code>x</code>	an object inheriting from class "somgrid" or "SOM".
<code>type, ...</code>	graphical parameters.

**Details**

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a [stars](#) plot of the representative at each grid point.

**Value**

For somgrid, an object of class "somgrid", a list with components

pts	a two-column matrix giving locations for the grid points.
xdim, ydim, topo	as in the arguments to somgrid.

## Chapter 20

# The `cluster` package

---

`agnes`

*Agglomerative Nesting (Hierarchical Clustering)*

---

### Description

Computes agglomerative hierarchical clustering of the dataset.

### Usage

```
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
      stand = FALSE, method = "average", par.method,
      keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

### Arguments

<code>x</code>	<p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector with length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p>
<code>diss</code>	<p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.</p>
<code>metric</code>	<p>character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>
<code>stand</code>	<p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable</p>

	(column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored.
<code>method</code>	character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-]group [arithMetic] average method, aka 'UPGMA'), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the <code>par.method</code> argument, and "gaverage" a generalized "average" aka "flexible UPGMA" method also using the Lance-Williams formula and <code>par.method</code> . The default is "average".
<code>par.method</code>	If <code>method</code> is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for "gaverage"), see in the details section.
<code>keep.diss, keep.data</code>	logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .
<code>trace.lev</code>	integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.

## Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two *nearest* clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method = "flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters  $C_1$  and  $C_2$  are agglomerated into a new cluster, the dissimilarity between their union and another cluster  $Q$  is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients  $(\alpha_1, \alpha_2, \beta, \gamma)$  are specified by the vector `par.method`, either directly as vector of length 4, or (more conveniently) if `par.method` is of length 1, say  $= \alpha$ , `par.method` is extended to give the "Flexible Strategy" (K&R(1990), p.236 f) with Lance-Williams coefficients  $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$ .

Also, if `length(par.method) == 3`,  $\gamma = 0$  is set.

**Care** and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. Since **cluster** version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The *weighted average* (`method="weighted"`) is the same as `method="flexible", par.method = 0.5`. Further, `method= "single"` is equivalent to `method="flexible", par.method = c(.5,.5,0,-.5)`, and `method="complete"` is equivalent to `method="flexible", par.method = c(.5,.5,0,+.5)`.

The `method = "gaverage"` is a generalization of "average", aka "flexible UPGMA" method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with  $\alpha_1$  and  $\alpha_2$  not constant, but *proportional* to the sizes  $n_1$  and  $n_2$  of the clusters  $C_1$  and  $C_2$  respectively, i.e.,

$$\alpha_j = \alpha'_j \frac{n_1}{n_1 + n_2},$$

where  $\alpha'_1, \alpha'_2$  are determined from `par.method`, either directly as  $(\alpha_1, \alpha_2, \beta, \gamma)$  or  $(\alpha_1, \alpha_2, \beta)$  with  $\gamma = 0$ , or (less flexibly, but more conveniently) as follows:

Belbin et al proposed "flexible beta", i.e. the user would only specify  $\beta$  (as `par.method`), sensibly in

$$-1 \leq \beta < 1,$$

and  $\beta$  determines  $\alpha'_1$  and  $\alpha'_2$  as

$$\alpha'_j = 1 - \beta,$$

and  $\gamma = 0$ .

This  $\beta$  may be specified by `par.method` (as length 1 vector), and if `par.method` is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a  $\beta$  value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that `method = "gaverage", par.method = 0` (or `par.method = c(1, 1, 0, 0)`) is equivalent to the `agnes()` default method "average".

## Value

an object of class "agnes" (which extends "twins") representing the clustering. See [agnes.object](#) for details, and methods applicable.

## BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

**Hierarchical methods** like `agnes`, `diana`, and `mona` construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

**Partitioning methods** like `pam`, `clara`, and `fanny` require that the number of clusters be given by the user.

## Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

```

---

 agnes.object

---

*Agglomerative Nesting (AGNES) Object*

---

## Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

## Value

A legitimate agnes object is a list with the following components:

order	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
order.lab	a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
height	a vector with the distances between merging clusters at the successive stages.
ac	the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The <code>ac</code> is the average of all $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>ac</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
merge	an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the merging of clusters at step $i$ of the clustering. If a number $j$ in the row is negative, then the single observation $ j $ is merged at this stage. If $j$ is positive, then the merger is with the cluster formed at stage $j$ of the algorithm.
diss	an object of class "dissimilarity" (see <a href="#">dissimilarity.object</a> ), representing the total dissimilarity matrix of the dataset.
data	a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.

GENERATION

This class of objects is returned from `agnes`.

METHODS

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`, and `as.dendrogram`.  
In addition, `cutree(x, *)` can be used to “cut” the dendrogram in order to produce cluster assignments.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for agnes objects. After applying `as.hclust()`, all *its* methods are available, of course.

See Also

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`, `cutree`.

Examples

```
data(agriculture)
ag.ag <- agnes(agriculture)
class(ag.ag)
pltree(ag.ag) # the dendrogram

## cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(ag.ag, k = 3))
(ch6 <- cutree(as.hclust(ag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))
```

---

agriculture	<i>European Union Agricultural Workforces</i>
-------------	---

---

Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

```
data(agriculture)
```

Format

A data frame with 12 observations on 2 variables:

[ , 1]	x	numeric	per capita GNP
[ , 2]	y	numeric	percentage in agriculture

The row names of the data frame indicate the countries.

### Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

### Source

Eurostat (European Statistical Agency, 1994): *Cijfers en feiten: Een statistisch portret van de Europese Unie*.

### References

see those in [agnes](#).

### See Also

[agnes](#), [daisy](#), [diana](#).

### Examples

```
data(agriculture)

## Compute the dissimilarities using Euclidean metric and without
## standardization
daisy(agriculture, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(agriculture, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
## Not run: plot(agnes(agriculture), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

animals

*Attributes of Animals*

---

### Description

This data set considers 6 binary attributes for 20 animals.

### Usage

```
data(animals)
```

### Format

A data frame with 20 observations on 6 variables:

[ , 1]	war	warm-blooded
[ , 2]	fly	can fly
[ , 3]	ver	vertebrate
[ , 4]	end	endangered
[ , 5]	gro	live in groups
[ , 6]	hai	have hair

All variables are encoded as 1 = ‘no’, 2 = ‘yes’.

### Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

### Source

Leonard Kaufman and Peter J. Rousseeuw (1990): *Finding Groups in Data* (pp 297ff). New York: Wiley.

### References

see Struyf, Hubert & Rousseeuw (1996), in [agnes](#).

### Examples

```
data(animals)
apply(animals, 2, table) # simple overview

ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

---

bannerplot

*Plot Banner (of Hierarchical Clustering)*

---

### Description

Draws a “banner”, i.e. basically a horizontal [barplot](#) visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

### Usage

```
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
           main=NULL, sub=NULL, xlab = "Height", adj = 0,
           col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
           rev.xax = !fromLeft, xax.pretty = TRUE,
           labels = NULL, nmax.lab = 35, max.strlen = 5,
           yax.do = axes && length(x$order) <= nmax.lab,
           yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
```

**Arguments**

<code>x</code>	a list with components <code>order</code> , <code>order.lab</code> and <code>height</code> when <code>w</code> , the next argument is not specified.
<code>w</code>	non-negative numeric vector of bar widths.
<code>fromLeft</code>	logical, indicating if the banner is from the left or not.
<code>main, sub</code>	main and sub titles, see <a href="#">title</a> .
<code>xlab</code>	x axis label (with ‘correct’ default e.g. for <code>plot.agnes</code> ).
<code>adj</code>	passed to <a href="#">title</a> ( <code>main, sub</code> ) for string adjustment.
<code>col</code>	vector of length 2, for two horizontal segments.
<code>border</code>	color for bar border; now defaults to background (no border).
<code>axes</code>	logical indicating if axes (and labels) should be drawn at all.
<code>frame.plot</code>	logical indicating the banner should be framed; mainly used when <code>border = 0</code> (as per default).
<code>rev.xax</code>	logical indicating if the x axis should be reversed (as in <code>plot.diana</code> ).
<code>xax.pretty</code>	logical or integer indicating if <a href="#">pretty()</a> should be used for the x axis. <code>xax.pretty = FALSE</code> is mainly for back compatibility.
<code>labels</code>	labels to use on y-axis; the default is constructed from <code>x</code> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in banner plot labeling.
<code>yax.do</code>	logical indicating if a y axis and banner labels should be drawn.
<code>yaxRight</code>	logical indicating if the y axis is on the right or left.
<code>y.mar</code>	positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font.
<code>...</code>	graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.

**Note**

This is mainly a utility called from [plot.agnes](#), [plot.diana](#) and [plot.mona](#).

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).

**Examples**

```
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```

---

chorSub*Subset of C-horizon of Kola Data*

---

## Description

This is a small rounded subset of the C-horizon data [chorizon](#) from package **mvoutlier**.

## Usage

```
data(chorSub)
```

## Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

## Details

This data set was produced from `chorizon` via these statements:

```
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", "", colnames(chorSub))
```

## Source

Kola Project (1993-1998)

## See Also

[chorizon](#) in package **mvoutlier** and other Kola data in the same package.

## Examples

```
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```

## Description

Computes a "clara" object, a list representing a clustering of the data into  $k$  clusters.

## Usage

```
clara(x, k, metric = "euclidean", stand = FALSE, samples = 5,
      sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
      keep.data = medoids.x, rngR = FALSE, pamLike = FALSE)
```

## Arguments

<code>x</code>	data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
<code>k</code>	integer, the number of clusters. It is required that $0 < k < n$ where $n$ is the number of observations (i.e., $n = \text{nrow}(x)$ ).
<code>metric</code>	character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.
<code>stand</code>	logical, indicating if the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.
<code>samples</code>	integer, number of samples to be drawn from the dataset. The default, 5, is rather small for historical (and now back compatibility) reasons and we recommend to set <code>samples</code> an order of magnitude larger.
<code>sampsize</code>	integer, number of observations in each sample. <code>sampsize</code> should be higher than the number of clusters ( $k$ ) and at most the number of observations ( $n = \text{nrow}(x)$ ).
<code>trace</code>	integer indicating a <i>trace level</i> for diagnostic output during the algorithm.
<code>medoids.x</code>	logical indicating if the medoids should be returned, identically to some rows of the input data <code>x</code> . If <code>FALSE</code> , <code>keep.data</code> must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned ( <code>i.med</code> component), and the algorithm saves space by needing one copy less of <code>x</code> .
<code>keep.data</code>	logical indicating if the ( <i>scaled</i> if <code>stand</code> is true) data should be kept in the result. Setting this to <code>FALSE</code> saves memory (and hence time), but disables <code>clusplot()</code> ing of the result. Use <code>medoids.x = FALSE</code> to save even more memory.
<code>rngR</code>	logical indicating if R's random number generator should be used instead of the primitive <code>clara()</code> -builtin one. If true, this also means that each call to <code>clara()</code> returns a different result – though only slightly different in good situations.

`pamLike` logical indicating if the “swap” phase (see `pam`, in C code) should use the same algorithm as `pam()`. Note that from Kaufman and Rousseeuw’s description this *should* have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, `pamLike = FALSE` has been chosen to remain back compatible rather than “PAM compatible”.

## Details

`clara` is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as `pam`, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (`sampsize`) such that the time and storage requirements become linear in  $n$  rather than quadratic.

Each sub-dataset is partitioned into  $k$  clusters using the same algorithm as in `pam`.

Once  $k$  representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until `sampsize` has been reached.

## Value

an object of class "`clara`" representing the clustering. See `clara.object` for details.

## Note

By default, the random sampling is implemented with a *very* simple scheme (with period  $2^{16} = 65536$ ) inside the Fortran code, independently of R’s random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting `rngR = TRUE` which uses R’s random number generators. Then, `clara()` results are made reproducible typically by using `set.seed()` before calling `clara`.

The storage requirement of `clara` computation (for small  $k$ ) is about  $O(n \times p) + O(j^2)$  where  $j = \text{sampsize}$ , and  $(n, p) = \text{dim}(x)$ . The CPU computing time (again assuming small  $k$ ) is about  $O(n \times p \times j^2 \times N)$ , where  $N = \text{samples}$ .

For “small” datasets, the function `pam` can be used directly. What can be considered *small*, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “*small (say with fewer than 200 observations)*”; as of 2006, you can use `pam` with several thousand observations.

## Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. All arguments from `trace` on, and most R documentation and all tests by Martin Maechler.

## See Also

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

## Examples

```
## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
           cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
## using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
          clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)

## `xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## "better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
## but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)

## Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421) # (reproducibility)
cl <- matrix(NA, nrow(xclara), nSim)
for(i in 1:nSim)
  cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
tcl <- apply(cl, 1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl, 2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
  tabD <- tcl[,iDoubt, drop=FALSE]
  dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
  t(tabD) # how many times in which clusters
}
```

---

clara.object

---

*Clustering Large Applications (CLARA) Object*

---

## Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from [clara](#).

## Value

A legitimate clara object is a list with the following components:

sample	labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.
--------	---

medoids	the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from <code>clara(*, medoids.x=FALSE)</code> . Use the following <code>i.med</code> in that case.
i.med	the <i>indices</i> of the medoids above: <code>medoids &lt;- x[i.med,]</code> where <code>x</code> is the original data matrix in <code>clara(x, *)</code> .
clustering	the clustering vector, see <a href="#">partition.object</a> .
objective	the objective function for the final clustering of the entire dataset.
clusinfo	matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster's medoid, divided by the minimal dissimilarity between the cluster's medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters.
diss	dissimilarity (maybe NULL), see <a href="#">partition.object</a> .
silinfo	list with silhouette width information for the best sample, see <a href="#">partition.object</a> .
call	generating call, see <a href="#">partition.object</a> .
data	matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .

### Methods, Inheritance

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a clara object.

### See Also

[clara](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

---

clusGap

*Gap Statistic for Estimating the Number of Clusters*

---

### Description

`clusGap()` calculates a goodness of clustering measure, the "gap" statistic. For each number of clusters  $k$ , it compares  $\log(W(k))$  with  $E^*[\log(W(k))]$  where the latter is defined via bootstrapping, i.e. simulating from a reference distribution.

`maxSE(f, SE.f)` determines the location of the **maximum** of  $f$ , taking a "1-SE rule" into account for the `*SE*` methods. The default method "firstSEmax" looks for the smallest  $k$  such that its value  $f(k)$  is not more than 1 standard error away from the first local maximum. This is similar but not the same as "Tibs2001SEmax", Tibshirani et al's recommendation of determining the number of clusters from the gap statistics and their standard deviations.

## Usage

```
clusGap(x, FUNcluster, K.max, B = 100, verbose = interactive(), ...)

maxSE(f, SE.f,
      method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax",
                  "firstmax", "globalmax"),
      SE.factor = 1)
## S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)
```

## Arguments

x	numeric matrix or <code>data.frame</code> .
FUNcluster	a <code>function</code> which accepts as first argument a (data) matrix like x, second argument, say $k, k \geq 2$ , the number of clusters desired, and returns a <code>list</code> with a component named (or shortened to) <code>cluster</code> which is a vector of length $n = \text{nrow}(x)$ of integers in $1:k$ determining the clustering or grouping of the $n$ observations.
K.max	the maximum number of clusters to consider, must be at least two.
B	integer, number of Monte Carlo (“bootstrap”) samples.
verbose	integer or logical, determining if “progress” output should be printed. The default prints one bit per bootstrap sample.
...	optionally further arguments for <code>FUNcluster()</code> , see <code>kmeans</code> example below.
f	numeric vector of ‘function values’, of length $K$ , whose (“1 SE respected”) maximum we want.
SE.f	numeric vector of length $K$ of standard errors of $f$ .
method	<p>character string indicating how the “optimal” number of clusters, <math>\hat{k}</math>, is computed from the gap statistics (and their standard deviations), or more generally how the location <math>\hat{k}</math> of the maximum of <math>f_k</math> should be determined.</p> <p>"globalmax": simply corresponds to the global maximum, i.e., is <code>which.max(f)</code></p> <p>"firstmax": gives the location of the first <i>local</i> maximum.</p> <p>"Tibs2001SEmax": uses the criterion, Tibshirani et al (2001) proposed: “the smallest <math>k</math> such that <math>f(k) \geq f(k+1) - s_{k+1}</math>”. Note that this chooses <math>k = 1</math> when all standard deviations are larger than the differences <math>f(k+1) - f(k)</math>.</p> <p>"firstSEmax": location of the first <math>f()</math> value which is not larger than the first <i>local</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>"globalSEmax": (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani’s proposition): location of the first <math>f()</math> value which is not larger than the <i>global</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>See the examples for a comparison in a simple case.</p>
SE.factor	[When method contains "SE"] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an <code>SE.factor f</code> , the “f S.E.”-rule is used, more generally.

## Details

The main result `<res>$Tab[, "gap"]` of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see `set.seed()`). On the other hand, in our experience, using `B = 500` gives quite precise results such that the gap plot is basically unchanged after an another run.

## Value

an object of S3 class `"clusGap"`, basically a list with components

Tab	a matrix with <code>K.max</code> rows and 4 columns, named "logW", "E.logW", "gap", and "SE.sim", where <code>gap = E.logW - logW</code> , and <code>SE.sim</code> corresponds to the standard error of gap, <code>SE.sim[k] = s<sub>k</sub></code> , where $s_k := \sqrt{1 + 1/B} sd^*(gap_j)$ , and <code>sd^*</code> () is the standard deviation of the simulated ("bootstrapped") gap values.
n	number of observations, i.e., <code>nrow(x)</code> .
B	input B
FUNcluster	input function FUNcluster

## Author(s)

This function is originally based on the functions `gap` of (Bioconductor) package **SAGx** by Per Broberg, `gapStat()` from former package **SLmisc** by Matthias Kohl and ideas from `gap()` and its methods of package **lga** by Justin Harrington.

The current implementation is by Martin Maechler.

## Slightly faster way to use pam (see below)
pam1 <- function(x,k) list(cluster = pam(x,k, cluster.only=TRUE))

doExtras <- cluster::doExtras()
## or set it explicitly to TRUE for the following
if(doExtras) {
  ## Note we use B = 60 in the following examples to keep them "speedy".
  ## ---- rather keep the default B = 500 for your analysis!

  ## note we can pass 'nstart = 20' to kmeans() :
  gskmn <- clusGap(x, FUN = kmeans, nstart = 20, K.max = 8, B = 60)
  gskmn #-> its print() method
  plot(gskmn, main = "clusGap(., FUN = kmeans, n.start=20, B= 60)")
  set.seed(12); system.time(
    gsPam0 <- clusGap(x, FUN = pam, K.max = 8, B = 60)
  )
  set.seed(12); system.time(
    gsPam1 <- clusGap(x, FUN = pam1, K.max = 8, B = 60)
  )
  ## and show that it gives the same:
  stopifnot(identical(gsPam1[-4], gsPam0[-4]))
  gsPam1
  print(gsPam1, method="globalSEmax")
  print(gsPam1, method="globalmax")
}

gs.pam.RU <- clusGap(ruspini, FUN = pam1, K.max = 8, B = 60)
gs.pam.RU
plot(gs.pam.RU, main = "Gap statistic for the 'ruspini' data")
mtext("k = 4 is best .. and k = 5 pretty close")

## This takes a minute..
## No clustering ==> k = 1 ("one cluster") should be optimal:
Z <- matrix(rnorm(256*3), 256,3)
gsP.Z <- clusGap(Z, FUN = pam1, K.max = 8, B = 200)
plot(gsP.Z)
gsP.Z
```

## Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

**Usage**

```
clusplot(x, ...)

## S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)
```

**Arguments**

x	an R object, here, specifically an object of class "partition", e.g. created by one of the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .
main	title for the plot; when NULL (by default), a title is constructed, using <code>x\$call</code> .
dist	when x does not have a <code>diss</code> nor a <code>data</code> component, e.g., for <a href="#">pam</a> ( <code>dist(*)</code> , <code>keep.diss=FALSE</code> ), <code>dist</code> must specify the dissimilarity for the <code>clusplot</code> .
...	optional arguments passed to methods, notably the <a href="#">clusplot.default</a> method (except for the <code>diss</code> one) may also be supplied to this function. Many graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments here.

**Details**

The `clusplot.partition()` method relies on [clusplot.default](#).

If the clustering algorithms `pam`, `fanny` and `clara` are applied to a data matrix of observations-by-variables then a `clusplot` of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with [pam](#) or [fanny](#), the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm `clara` was applied to a data matrix with NAs then `clusplot` will replace the missing values as described in [clusplot.default](#), because a dissimilarity matrix is not available.

**Value**

For the `partition` (and `default`) method: An invisible list with components `Distances` and `Shading`, as for [clusplot.default](#), see there.

**Side Effects**

a 2-dimensional `clusplot` is created on the current graphics device.

**See Also**

[clusplot.default](#) for references; [partition.object](#), [pam](#), [pam.object](#), [clara](#), [clara.object](#), [fanny](#), [fanny.object](#), [par](#).

**Examples**

```
## For more, see ?clusplot.default

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

---

clusplot.default     *Bivariate Cluster Plot (clusplot) Default Method*

---

## Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

## Usage

```
## Default S3 method:
clusplot(x, clus, diss = FALSE,
         s.x.2d = mkCheckX(x, diss), stand = FALSE,
         lines = 2, shade = FALSE, color = FALSE,
         labels = 0, plotchar = TRUE,
         col.p = "dark green", col.txt = col.p,
         col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
         span = TRUE,
         add = FALSE,
         xlim = NULL, ylim = NULL,
         main = paste("CLUSPLOT(", deparse(substitute(x)), ")"),
         sub = paste("These two components explain",
                     round(100 * var.dec, digits = 2), "% of the point variability."),
         xlab = "Component 1", ylab = "Component 2",
         verbose = getOption("verbose"),
         ...)
```

## Arguments

<code>x</code>	matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.  In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.  In case of a dissimilarity matrix, <code>x</code> is the output of <a href="#">daisy</a> or <a href="#">dist</a> or a symmetric matrix. Also, a vector of length $n * (n - 1) / 2$ is allowed (where $n$ is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.
<code>clus</code>	a vector of length $n$ representing a clustering of <code>x</code> . For each observation the vector lists the number or name of the cluster to which it has been assigned. <code>clus</code> is often the clustering component of the output of <a href="#">pam</a> , <a href="#">fanny</a> or <a href="#">clara</a> .
<code>diss</code>	logical indicating if <code>x</code> will be considered as a dissimilarity matrix or a matrix of observations by variables (see <code>x</code> argument above).
<code>s.x.2d</code>	a <a href="#">list</a> with components named <code>x</code> (a $n \times 2$ matrix; typically something like principal components of original data), <code>labs</code> and <code>var.dec</code> .
<code>stand</code>	logical flag: if true, then the representations of the $n$ observations in the 2-dimensional plot are standardized.

lines	<p>integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. The distance between two ellipses E1 and E2 is measured along the line connecting the centers <math>m1</math> and <math>m2</math> of the two ellipses.</p> <p>In case E1 and E2 overlap on the line through <math>m1</math> and <math>m2</math>, no line is drawn. Otherwise, the result depends on the value of lines: If</p> <p><b>lines = 0</b>, no distance lines will appear on the plot;</p> <p><b>lines = 1</b>, the line segment between <math>m1</math> and <math>m2</math> is drawn;</p> <p><b>lines = 2</b>, a line segment between the boundaries of E1 and E2 is drawn (along the line connecting <math>m1</math> and <math>m2</math>).</p>
shade	<p>logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.</p>
color	<p>logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).</p>
labels	<p>integer code, currently one of 0,1,2,3,4 and 5. If</p> <p><b>labels= 0</b>, no labels are placed in the plot;</p> <p><b>labels= 1</b>, points and ellipses can be identified in the plot (see <code>identify</code>);</p> <p><b>labels= 2</b>, all points and ellipses are labelled in the plot;</p> <p><b>labels= 3</b>, only the points are labelled in the plot;</p> <p><b>labels= 4</b>, only the ellipses are labelled in the plot.</p> <p><b>labels= 5</b>, the ellipses are labelled in the plot, and points can be identified.</p> <p>The levels of the vector <code>clus</code> are taken as labels for the clusters. The labels of the points are the rownames of <code>x</code> if <code>x</code> is matrix like. Otherwise (<code>diss = TRUE</code>), <code>x</code> is a vector, point labels can be attached to <code>x</code> as a "Labels" attribute (<code>attr(x, "Labels")</code>), as is done for the output of <code>daisy</code>.</p> <p>A possible <code>names</code> attribute of <code>clus</code> will not be taken into account.</p>
plotchar	<p>logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.</p>
span	<p>logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.)</p> <p>If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse.</p> <p>There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, <code>span=FALSE</code> draws a narrow ellipse around it and <code>span=TRUE</code> gives the exact line segment.</p>
add	<p>logical indicating if ellipses (and labels if <code>labels</code> is true) should be <i>added</i> to an already existing plot. If false, neither a <code>title</code> or sub title, see <code>sub</code>, is written.</p>
col.p	<p>color code(s) used for the observation points.</p>
col.txt	<p>color code(s) used for the labels (if <code>labels &gt;= 2</code>).</p>
col.clus	<p>color code for the ellipses (and their labels); only one if color is false (as per default).</p>
cex, cex.txt	<p>character <b>expansion</b> (size), for the point symbols and point labels, respectively.</p>
xlim, ylim	<p>numeric vectors of length 2, giving the x- and y- ranges as in <code>plot.default</code>.</p>

<code>main</code>	main title for the plot; by default, one is constructed.
<code>sub</code>	sub title for the plot; by default, one is constructed.
<code>xlab, ylab</code>	x- and y- axis labels for the plot, with defaults.
<code>verbose</code>	a logical indicating, if there should be extra diagnostic output; mainly for ‘debugging’.
<code>...</code>	Further graphical parameters may also be supplied, see <code>par</code> .

### Details

`clusplot` uses the functions `princomp` and `cmdscale`. These functions are data reduction techniques. They will represent the data in a bivariate plot. Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

### Value

An invisible list with components:

<code>Distances</code>	When <code>lines</code> is 1 or 2 we obtain a $k$ by $k$ matrix ( $k$ is the number of clusters). The element in $[i, j]$ is the distance between ellipse $i$ and ellipse $j$ . If <code>lines</code> = 0, then the value of this component is NA.
<code>Shading</code>	A vector of length $k$ (where $k$ is the number of clusters), containing the amount of shading per cluster. Let $y$ be a vector where element $i$ is the ratio between the number of points in cluster $i$ and the area of ellipse $i$ . When the cluster $i$ is a line segment, $y[i]$ and the density of the cluster are set to NA. Let $z$ be the sum of all the elements of $y$ without the NAs. Then we put <code>shading</code> = $y/z * 37 + 3$ .

### Side Effects

a visual display of the clustering is plotted on the current graphics device.

### Note

When we have 4 or fewer clusters, then the `color=TRUE` gives every cluster a different color. When there are more than 4 clusters, `clusplot` uses the function `pam` to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. `col.clus` specifies the colors used.

The `col.p` and `col.txt` arguments, added for R, are recycled to have length the number of observations. If `col.p` has more than one value, using `color = TRUE` can be confusing because of a mix of point and ellipse colors.

```

coef.hclust

*Agglomerative / Divisive Coefficient for 'hclust' Objects*

## Description

Computes the “agglomerative coefficient” (aka “divisive coefficient” for [diana](#)), measuring the clustering structure of the dataset.

For each observation  $i$ , denote by  $m(i)$  its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all  $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot.

`coefHier()` directly interfaces to the underlying C code, and “proves” that *only* `object$heights` is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

## Usage

```

coefHier(object)
coef.hclust(object, ...)
## S3 method for class 'hclust'
coef(object, ...)
## S3 method for class 'twins'
coef(object, ...)

```

## Arguments

`object` an object of class "hclust" or "twins", i.e., typically the result of [hclust\(.\)](#), [agnes\(.\)](#), or [diana\(.\)](#).

Since `coef.hclust` only uses `object$heights`, and `object$merge`, `object` can be any list-like object with appropriate merge and heights components.

For `coefHier`, even only `object$heights` is needed.

`...` currently unused potential further arguments

## Value

a number specifying the *agglomerative* (or *divisive* for `diana` objects) coefficient as defined by Kaufman and Rousseeuw, see [agnes.object \\$ ac](#) or [diana.object \\$ dc](#).

Examples

```
data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa)) # recomputes
coefHier(aa) # ditto
```

---

daisy	<i>Dissimilarity Matrix Calculation</i>
-------	---

---

Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever `metric = "gower"` is set, a generalization of Gower’s formula is used, see ‘Details’ below.

Usage

```
daisy(x, metric = c("euclidean", "manhattan", "gower"),
      stand = FALSE, type = list(), weights = rep.int(1, p))
```

Arguments

x	numeric matrix or data frame, of dimension $n \times p$ , say. Dissimilarities will be computed between the rows of x. Columns of mode <code>numeric</code> (i.e. all columns when x is a matrix) will be recognized as interval scaled variables, columns of class <code>factor</code> will be recognized as nominal variables, and columns of class <code>ordered</code> will be recognized as ordinal variables. Other variable types should be specified with the <code>type</code> argument. Missing values (NAs) are allowed.
metric	character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. “Gower’s distance” is chosen by metric "gower" or automatically if some columns of x are not numeric. Also known as Gower’s coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the “distance” between two units is the sum of all the variable-specific distances, see the details section.
stand	logical flag: if TRUE, then the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If not all columns of x are numeric, stand will be ignored and Gower’s standardization (based on the <a href="#">range</a> ) will be applied in any case, see argument <code>metric</code> , above, and the details section.
type	list for specifying some (or all) of the types of the variables (columns) in x. The list may contain the following components: "ordratio" (ratio scaled variables to be treated as ordinal variables), "logratio" (ratio scaled variables that must be logarithmically transformed), "asymm" (asymmetric binary) and

"`symm`" (symmetric binary variables). Each component's value is a vector, containing the names or the numbers of the corresponding columns of `x`. Variables not mentioned in the `type` list are interpreted as usual (see argument `x`).

`weights` an optional numeric vector of length  $p(=ncol(x))$ ; to be used in "case 2" (mixed variables, or `metric = "gower"`), specifying a weight for each variable (`x[,k]`) instead of 1 in Gower's original formula.

## Details

The original version of `daisy` is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to `dist` whose input must be numeric variables, the main feature of `daisy` is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If `x` contains any columns of these data-types, both arguments `metric` and `stand` will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by `metric = "gower"`. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range  $[0, 1]$ , exactly.

Note that setting the type to `symm` (symmetric binary) gives the same dissimilarities as using `nominal` (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that `daisy` now gives a warning when 2-valued numerical variables do not have an explicit type specified, because the reference authors recommend to consider using `asymm`.

In the `daisy` algorithm, missing values in a row of `x` are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and `metric` is *not* "gower"), the metric is "euclidean", and  $n_g$  is the number of columns in which neither row  $i$  and  $j$  have NAs, then the dissimilarity  $d(i,j)$  returned is  $\sqrt{p/n_g}$  ( $p = ncol(x)$ ) times the Euclidean distance between the two vectors of length  $n_g$  shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is  $p/n_g$ . If  $n_g = 0$ , the dissimilarity is NA.
2. When some variables have a type other than interval scaled, or if `metric = "gower"` is specified, the dissimilarity between two rows is the weighted mean of the contributions of each variable. Specifically,

$$d_{ij} = d(i, j) = \frac{\sum_{k=1}^p w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^p w_k \delta_{ij}^{(k)}}.$$

In other words,  $d_{ij}$  is a weighted mean of  $d_{ij}^{(k)}$  with weights  $w_k \delta_{ij}^{(k)}$ , where  $w_k = weights[k]$ ,  $\delta_{ij}^{(k)}$  is 0 or 1, and  $d_{ij}^{(k)}$ , the  $k$ -th variable contribution to the total distance, is a distance between `x[i, k]` and `x[j, k]`, see below.

The 0-1 weight  $\delta_{ij}^{(k)}$  becomes zero when the variable `x[, k]` is missing in either or both rows ( $i$  and  $j$ ), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution  $d_{ij}^{(k)}$  of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that "standard scoring" is applied to ordinal variables, i.e., they are replaced by their integer codes  $1:K$ . Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions  $d_{ij}^{(k)}$  are in  $[0, 1]$ , the dissimilarity  $d_{ij}$  will remain in this range. If all weights  $w_k \delta_{ij}^{(k)}$  are zero, the dissimilarity is set to [NA](#).

### Value

an object of class "dissimilarity" containing the dissimilarities among the rows of `x`. This is typically the input for the functions `pam`, `fanny`, `agnes` or `diana`. For more details, see [dissimilarity.object](#).

### Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

### Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version.  
Martin Maechler improved the [NA](#) handling and `type` specification checking, and extended functionality to `metric = "gower"` and the optional `weights` argument.

summary(df13 <- daisy(flower,
  type = list(asymm = c("V1", "V3"), symm= 2,
    ordratio= 7, logratio= 8)))
```

diana

*Divisive ANALysis Clustering***Description**

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

**Usage**

```
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
      keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

**Arguments**

<code>x</code>	<p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) <i>are</i> allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p>
<code>diss</code>	<p>logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.</p>
<code>metric</code>	<p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>
<code>stand</code>	<p>logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>
<code>keep.diss, keep.data</code>	<p>logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i>.</p>
<code>trace.lev</code>	<p>integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.</p>

**Details**

`diana` is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, `diana` provides (a) the divisive coefficient (see `diana.object`) which

measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see `plot.diana`).

The `diana`-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all  $n$  observations. Clusters are divided until each cluster contains only a single observation.

At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

### Value

an object of class "diana" representing the clustering; this class has methods for the following generic functions: `print`, `summary`, `plot`.

Further, the class "diana" inherits from "twins". Therefore, the generic function `pltree` can be used on a diana object, and `as.hclust` and `as.dendrogram` methods are available.

A legitimate `diana` object is a list with the following components:

<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>height</code>	a vector with the diameters of the clusters prior to splitting.
<code>dc</code>	the divisive coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $d(i)$ the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The <code>dc</code> is the average of all $1 - d(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>dc</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
<code>merge</code>	an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the split at step $n-i$ of the clustering. If a number $j$ in row $r$ is negative, then the single observation $ j $ is split off at stage $n-r$ . If $j$ is positive, then the cluster that will be splitted at stage $n-j$ (described by row $j$ ), is split off at stage $n-r$ .
<code>diss</code>	an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.
<code>data</code>	a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.

### See Also

`agnes` also for background and references; `cutree` (and `as.hclust`) for grouping extraction; `daisy`, `dist`, `plot.diana`, `twins.object`.

**Examples**

```

data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2) ## identical group assignments

str(as.dendrogram(dv0)) # {via as.dendrogram.twins() method}

data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)

```

dissimilarity.object

*Dissimilarity Matrix Object*

---

**Description**

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

**Value**

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called `do`, and `n` the number of observations, i.e., `n <- attr(do, "Size")`, then for  $i < j \leq n$ , the dissimilarity between (row)  $i$  and  $j$  is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is  $n * (n - 1) / 2$ , i.e., of order  $n^2$ .

"dissimilarity" objects also inherit from class `dist` and can use `dist` methods, in particular, `as.matrix`, such that  $d_{ij}$  from above is just `as.matrix(do)[i, j]`.

The object has the following attributes:

Size	the number of observations in the dataset.
Metric	the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".
Labels	optionally, contains the labels, if any, of the observations of the dataset.
NA.message	optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.
Types	when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54):

**A** Asymmetric binary  
**S** Symmetric binary  
**N** Nominal (factor)  
**O** Ordinal (ordered factor)  
**I** Interval scaled (numeric)  
**T** raTio to be log transformed (positive numeric)  
 .

## GENERATION

`daisy` returns this class of objects. Also the functions `pam`, `clara`, `fanny`, `agnes`, and `diana` return a dissimilarity object, as one component of their return objects.

## METHODS

The "dissimilarity" class has methods for the following generic functions: `print`, `summary`.

## See Also

`daisy`, `dist`, `pam`, `clara`, `fanny`, `agnes`, `diana`.

---

ellipsoidhull

*Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set*

---

## Description

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

## Usage

```
ellipsoidhull(x, tol=0.01, maxit=5000,
              ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
## S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)
```

## Arguments

<code>x</code>	the $n$ $p$ -dimensional points as numeric $n \times p$ matrix.
<code>tol</code>	convergence tolerance for Titterton's algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase <code>maxit</code> as well.
<code>maxit</code>	integer giving the maximal number of iteration steps for the algorithm.
<code>ret.wt</code> , <code>ret.sqdist</code> , <code>ret.pr</code>	logicals indicating if additional information should be returned, <code>ret.wt</code> specifying the <i>weights</i> , <code>ret.sqdist</code> the <i>squared distances</i> and <code>ret.pr</code> the final <b>probabilities</b> in the algorithms.
<code>digits</code> , ...	the usual arguments to <code>print</code> methods.

## Details

The “spanning ellipsoid” algorithm is said to stem from Titterington(1976), in Pison et al (1999) who use it for `clusplot.default`.

The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more flexible and general implementation is `cov.mve` in the MASS package.

## Value

an object of class "ellipsoid", basically a `list` with several components, comprising at least

<code>cov</code>	$p \times p$ covariance matrix description the ellipsoid.
<code>loc</code>	$p$ -dimensional location of the ellipsoid center.
<code>d2</code>	average squared radius. Further, $d2 = t^2$ , where $t$ is “the value of a t-statistic on the ellipse boundary” (from <code>ellipse</code> in the <b>ellipse</b> package), and hence, more usefully, <code>d2 = qchisq(alpha, df = p)</code> , where <code>alpha</code> is the confidence level for $p$ -variate normally distributed data with location and covariance <code>loc</code> and <code>cov</code> to lie inside the ellipsoid.
<code>wt</code>	the vector of weights iff <code>ret.wt</code> was true.
<code>sqdist</code>	the vector of squared distances iff <code>ret.sqdist</code> was true.
<code>prob</code>	the vector of algorithm probabilities iff <code>ret.pr</code> was true.
<code>it</code>	number of iterations used.
<code>tol, maxit</code>	just the input argument, see above.
<code>eps</code>	the achieved tolerance which is the maximal squared radius minus $p$ .
<code>ierr</code>	error code as from the algorithm; 0 means <i>ok</i> .
<code>conv</code>	logical indicating if the converged. This is defined as <code>it &lt; maxit &amp;&amp; ierr == 0</code> .

## Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying code.

## See Also

`predict.ellipsoid` which is also the `predict` method for `ellipsoid` objects.  
`volume.ellipsoid` for an example of ‘manual’ `ellipsoid` object construction;  
 further `ellipse` from package **ellipse** and `ellipsePoints` from package **sfsmisc**.

`chull` for the convex hull, `clusplot` which makes use of this; `cov.mve`.

## Examples

```
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy <- ellipsoidhull(xy)
exy # >> calling print.ellipsoid()

plot(xy, main = "ellipsoidhull(<Gauss data>) -- 'spanning points'")
lines(predict(exy), col="blue")
points(rbind(exy$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small `tol`, hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
## --> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii], 3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2,
       col="blue", bg = adjustcolor("blue", 0.25))
```

---

fanny

---

*Fuzzy Analysis Clustering*

---

## Description

Computes a fuzzy clustering of the data into  $k$  clusters.

## Usage

```
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
      metric = c("euclidean", "manhattan", "SqEuclidean"),
      stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
      keep.diss = !diss && !cluster.only && n < 100,
      keep.data = !diss && !cluster.only,
      maxit = 500, tol = 1e-15, trace.lev = 0)
```

## Arguments

- |                   |   |
|-------------------|---|
| $x$               | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <math>x</math> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| $k$               | <p>integer giving the desired number of clusters. It is required that <math>0 &lt; k &lt; n/2</math> where <math>n</math> is the number of observations.</p>  |
| <code>diss</code> | <p>logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <math>x</math> is assumed to be a dissimilarity matrix. If FALSE, then <math>x</math> is treated as a matrix of observations by variables.</p>  |

<code>memb.exp</code>	number $r$ strictly larger than 1 specifying the <i>membership exponent</i> used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.
<code>metric</code>	character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the <i>squared</i> euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”. If $x$ is already a dissimilarity matrix, then this argument will be ignored.
<code>stand</code>	logical; if true, the measurements in $x$ are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored.
<code>iniMem.p</code>	numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.
<code>cluster.only</code>	logical; if true, no silhouette information will be computed and returned, see details.
<code>keep.diss, keep.data</code>	logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation <i>time</i> .
<code>maxit, tol</code>	maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults <code>maxit = 500</code> and <code>tol = 1e-15</code> used to be hardwired inside the algorithm.
<code>trace.lev</code>	integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.

## Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by  $u_{iv}$  the membership of observation  $i$  to cluster  $v$ .

The memberships are nonnegative, and for a fixed observation  $i$  they sum to 1. The particular method `fanny` stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in [daisy](#)) and has been extended by Martin Maechler to allow user specified `memb.exp`, `iniMem.p`, `maxit`, `tol`, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^k \frac{\sum_{i=1}^n \sum_{j=1}^n u_{iv}^r u_{jv}^r d(i,j)}{2 \sum_{j=1}^n u_{jv}^r}$$

where  $n$  is the number of observations,  $k$  is the number of clusters,  $r$  is the membership exponent `memb.exp` and  $d(i, j)$  is the dissimilarity between observations  $i$  and  $j$ .

Note that  $r \rightarrow 1$  gives increasingly crisper clusterings whereas  $r \rightarrow \infty$  leads to complete fuzziness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that

even the default,  $r = 2$  can lead to complete fuzzyness, i.e., memberships  $u_{iv} \equiv 1/k$ . In that case a warning is signalled and the user is advised to chose a smaller `memb.exp` ( $= r$ ).

Compared to other fuzzy clustering methods, `fanny` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the `spherical cluster` assumption; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`).

### Value

an object of class "fanny" representing the clustering. See `fanny.object` for details.

### See Also

`agnes` for background and references; `fanny.object`, `partition.object`, `plot.partition`, `daisy`, `dist`.

### Examples

```
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
           cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
           cbind(rnorm( 3, 3.2, 0.5), rnorm( 3, 3.2, 0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
(fanny(x, 2, memb.exp = 3))              # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

---

fanny.object

*Fuzzy Analysis (FANNY) Object*

---

### Description

The objects of class "fanny" represent a fuzzy clustering of a dataset.

### Value

A legitimate `fanny` object is a list with the following components:

<code>membership</code>	matrix containing the memberships for each pair consisting of an observation and a cluster.
<code>memb.exp</code>	the membership exponent used in the fitting criterion.

<code>coeff</code>	Dunn's partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all <i>squared</i> membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1. The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$ , and ranges between 0 and 1. A low value of Dunn's coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.
<code>clustering</code>	the clustering vector of the nearest crisp clustering, see <a href="#">partition.object</a> .
<code>k.crisp</code>	integer ( $\leq k$ ) giving the number of <i>crisp</i> clusters; can be less than $k$ , where it's recommended to decrease <code>memb.exp</code> .
<code>objective</code>	named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance <code>tol</code> used.
<code>convergence</code>	named vector with <code>iterations</code> , the number of iterations needed and <code>converged</code> indicating if the algorithm converged (in <code>maxit</code> iterations within convergence tolerance <code>tol</code> ).
<code>diss</code>	an object of class "dissimilarity", see <a href="#">partition.object</a> .
<code>call</code>	generating call, see <a href="#">partition.object</a> .
<code>silinfo</code>	list with silhouette information of the nearest crisp clustering, see <a href="#">partition.object</a> .
<code>data</code>	matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .

## GENERATION

These objects are returned from [fanny](#).

## METHODS

The "fanny" class has methods for the following generic functions: `print`, `summary`.

## INHERITANCE

The class "fanny" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a fanny object.

## See Also

[fanny](#), [print.fanny](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

---

flower

*Flower Characteristics*

---

## Description

8 characteristics for 18 popular flowers.

## Usage

```
data(flower)
```

**Format**

A data frame with 18 observations on 8 variables:

[ , "V1"]	factor	winters
[ , "V2"]	factor	shadow
[ , "V3"]	factor	tubers
[ , "V4"]	factor	color
[ , "V5"]	ordered	soil
[ , "V6"]	ordered	preference
[ , "V7"]	numeric	height
[ , "V8"]	numeric	distance

**V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.

**V2** shadow, is binary and shows whether the plant needs to stand in the shadow.

**V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.

**V4** color, is nominal and specifies the flower's color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).

**V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.

**V6** preference, is ordinal and gives someone's preference ranking going from 1 to 18.

**V7** height, is interval scaled, the plant's height in centimeters.

**V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

**References**

Struyf, Hubert and Rousseeuw (1996), see [agnes](#).

**Examples**

```
data(flower)
## Example 2 in ref
daisy(flower, type = list(asymm = 3))
daisy(flower, type = list(asymm = c(1, 3), ordratio = 7))
```

---

```
lower.to.upper.tri.inds
```

*Permute Indices for Triangular Matrices*

---

**Description**

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

**Usage**

```
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

**Arguments**

`n` integer larger than 1.

**Value**

integer vector containing a permutation of  $1:N$  where  $N = n(n-1)/2$ .

**See Also**

`upper.tri`, `lower.tri` with a related purpose.

**Examples**

```
m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
           lower.to.upper.tri.inds(3) == 1:3,
           upper.to.lower.tri.inds(3) == 1:3,
           sort(upper.to.lower.tri.inds(5)) == 1:10,
           sort(lower.to.upper.tri.inds(6)) == 1:15)
```

mona

*MONothetic Analysis Clustering of Binary Variables***Description**

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

**Usage**

```
mona(x)
```

**Arguments**

`x` data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from NA. No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical, is not allowed.

**Details**

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is "monothetic" in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are "polythetic", i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided

into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables  $f$  and  $g$  is given by  $a(f,g)*d(f,g) - b(f,g)*c(f,g)$ , where  $a(f,g)$ ,  $b(f,g)$ ,  $c(f,g)$ , and  $d(f,g)$  are the numbers in the contingency table of  $f$  and  $g$ . [That is,  $a(f,g)$  (resp.  $d(f,g)$ ) is the number of observations for which  $f$  and  $g$  both have value 0 (resp. value 1);  $b(f,g)$  (resp.  $c(f,g)$ ) is the number of observations for which  $f$  has value 0 (resp. 1) and  $g$  has value 1 (resp. 0).] The total association of a variable  $f$  is the sum of its associations to all variables.

This algorithm does not work with missing values, therefore the data are revised, e.g. all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable  $f$  has missing values, the variable  $g$  with the largest absolute association to  $f$  is looked up. When the association between  $f$  and  $g$  is positive, any missing value of  $f$  is replaced by the value of  $g$  for the same observation. If the association between  $f$  and  $g$  is negative, then any missing value of  $f$  is replaced by the value of  $1-g$  for the same observation.

### Value

an object of class "mona" representing the clustering. See `mona.object` for details.

### See Also

[agnes](#) for background and references; [mona.object](#), [plot.mona](#).

### Examples

```
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

## One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniNA <- within(animals, { end[2:9] <- NA })
if(getRversion() >= 3.0) {
  aniN2 <- animals; aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA }
ani.non2 <- within(animals, end[7] <- 3 )
ani.idNA <- within(animals, end[!is.na(end)] <- 1 )
try( mona(ani.NA) ) ## error: .. object with all values missing
try( mona(aniNA) ) ## error: .. more than half missing values
if(getRversion() >= 3.0)
try( mona(aniN2) ) ## error: all have at least one missing
try( mona(ani.non2) ) ## error: all must be binary
try( mona(ani.idNA) ) ## error: ditto
```

---

mona.object

*Monothetic Analysis (MONA) Object*

---

### Description

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from [mona](#).

**Value**

A legitimate `mona` object is a list with the following components:

<code>data</code>	matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>variable</code>	vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the variables used to separate the observations of <code>order</code> .
<code>step</code>	vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the separation steps at which the observations of <code>order</code> are separated.

**METHODS**

The "mona" class has methods for the following generic functions: `print`, `summary`, `plot`.

**See Also**

[mona](#) for examples etc, [plot.mona](#).

---

pam	<i>Partitioning Around Medoids</i>
-----	------------------------------------

---

**Description**

Partitioning (clustering) of the data into `k` clusters “around medoids”, a more robust version of K-means.

**Usage**

```
pam(x, k, diss = inherits(x, "dist"), metric = "euclidean",
    medoids = NULL, stand = FALSE, cluster.only = FALSE,
    do.swap = TRUE,
    keep.diss = !diss && !cluster.only && n < 100,
    keep.data = !diss && !cluster.only,
    pamonce = FALSE, trace.lev = 0)
```

**Arguments**

`x` data matrix or data frame, or dissimilarity matrix or object, depending on the value of the `diss` argument.

In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) *are* allowed—as long as every pair of observations has at least one case not missing.

In case of a dissimilarity matrix, `x` is typically the output of [daisy](#) or [dist](#). Also a vector of length  $n*(n-1)/2$  is allowed (where `n` is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are *not* allowed.

<code>k</code>	positive integer specifying the number of clusters, less than the number of observations.
<code>diss</code>	logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.
<code>metric</code>	character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.
<code>medoids</code>	NULL (default) or length- <code>k</code> vector of integer indices (in <code>1:n</code> ) specifying initial medoids instead of using the 'build' algorithm.
<code>stand</code>	logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.
<code>cluster.only</code>	logical; if true, only the clustering will be computed and returned, see details.
<code>do.swap</code>	logical indicating if the <b>swap</b> phase should happen. The default, TRUE, correspond to the original algorithm. On the other hand, the <b>swap</b> phase is much more computer intensive than the <b>build</b> one for large $n$ , so can be skipped by <code>do.swap = FALSE</code> .
<code>keep.diss, keep.data</code>	logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .
<code>pamonce</code>	logical or integer in <code>0:2</code> specifying algorithmic short cuts as proposed by Reynolds et al. (2006), see below.
<code>trace.lev</code>	integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.

## Details

The basic `pam` algorithm is fully described in chapter 2 of Kaufman and Rousseeuw(1990). Compared to the `k-means` approach in `kmeans`, the function `pam` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`) (d) it allows to select the number of clusters using `mean(silhouette(pr))` on the result `pr <- pam(..)`, or directly its component `pr$silinfo$avg.width`, see also `pam.object`.

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`pam(x, k, cluster.only=TRUE)` is the same as  
`pam(x, k)$clustering` but computed more efficiently.

The `pam`-algorithm is based on the search for  $k$  representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of  $k$  medoids,  $k$  clusters are constructed by assigning each observation to the nearest medoid. The goal is to find  $k$  representative objects which minimize the sum of the dissimilarities of the

observations to their closest representative object.

By default, when `medoids` are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid that will decrease the objective (this is called the **swap** phase).

When the `medoids` are specified, their order does *not* matter; in general, the algorithms have been designed to not depend on the order of the observations.

The `pamonce` option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006).

The default `FALSE` (or integer 0) corresponds to the original “swap” algorithm, whereas `pamonce = 1` (or `TRUE`), corresponds to the first proposal .... and `pamonce = 2` additionally implements the second proposal as well.

### Value

an object of class "pam" representing the clustering. See `?pam.object` for details.

### Note

For large datasets, `pam` may need too much memory or too much computation time since both are  $O(n^2)$ . Then, `clara()` is preferable, see its documentation.

### Author(s)

Kaufman and Rousseeuw's original Fortran code was translated to C and augmented in several ways, e.g. to allow `cluster.only=TRUE` or `do.swap=FALSE`, by Martin Maechler.  
Matthias Studer, Univ.Geneva provided the `pamonce` implementation.

### Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx
summary(pamx)
plot(pamx)
## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))
```

```
pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)

data(ruspini)
## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)
```

pam.object

*Partitioning Around Medoids (PAM) Object***Description**

The objects of class "pam" represent a partitioning of a dataset into clusters.

**Value**

A legitimate pam object is a [list](#) with the following components:

medoids	the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a <a href="#">matrix</a> with in each row the coordinates of one medoid.
id.med	integer vector of <i>indices</i> giving the medoid observation numbers.
clustering	the clustering vector, see <a href="#">partition.object</a> .
objective	the objective function after the first and second step of the pam algorithm.
isolation	vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated. A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.
clusinfo	matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).
silinfo	list with silhouette width information, see <a href="#">partition.object</a> .
diss	dissimilarity (maybe NULL), see <a href="#">partition.object</a> .
call	generating call, see <a href="#">partition.object</a> .
data	(possiblyly standardized) see <a href="#">partition.object</a> .

**GENERATION**

These objects are returned from [pam](#).

## METHODS

The "pam" class has methods for the following generic functions: `print`, `summary`.

## INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a pam object.

## See Also

[pam](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

## Examples

```
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
## Note that "k=1" won't work!
for (k in 2:20)
  asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type="h", main = "pam() clustering assessment",
     xlab= "k  (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

---

partition.object      *Partitioning Object*

---

## Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

## Value

a "partition" object is a list with the following (and typically more) components:

<code>clustering</code>	the clustering vector. An integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.
<code>call</code>	the matched <a href="#">call</a> generating the object.
<code>silinfo</code>	a list with all <i>silhouette</i> information, only available when the number of clusters is non-trivial, i.e., $1 < k < n$ and then has the following components, see <a href="#">silhouette</a>
<b>widths</b>	an $(n \times 3)$ matrix, as returned by <a href="#">silhouette()</a> , with for each observation $i$ the cluster to which $i$ belongs, as well as the neighbor cluster of $i$ (the cluster, not containing $i$ , for which the average dissimilarity between its observations and $i$ is minimal), and the silhouette width $s(i)$ of the observation.

	<b>clus.avg.widths</b> the average silhouette width per cluster.
	<b>avg.width</b> the average silhouette width for the dataset, i.e., simply the average of $s(i)$ over all observations $i$ .
	This information is also needed to construct a <i>silhouette plot</i> of the clustering, see <a href="#">plot.partition</a> .
	Note that <code>avg.width</code> can be maximized over different clusterings (e.g. with varying number of clusters) to choose an <i>optimal</i> clustering.
<code>objective</code>	value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.
<code>diss</code>	an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for <code>clara</code> ).
<code>data</code>	a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

GENERATION

These objects are returned from `pam`, `clara` or `fanny`.

METHODS

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See [pam.object](#), [clara.object](#) and [fanny.object](#) for details.

See Also

[pam](#), [clara](#), [fanny](#).

plantTraits	<i>Plant Species Traits Data</i>
-------------	----------------------------------

---

Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

Usage

`data(plantTraits)`

**Format**

A data frame with 136 observations on the following 31 variables.

pdias Diaspore mass (mg)  
 longindex Seed bank longevity  
 durflow Flowering duration  
 height Plant height, an ordered factor with levels 1 < 2 < ... < 8.  
 begflow Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9  
 mycor Mycorrhizas, an ordered factor with levels 0never < 1 sometimes < 2always  
 vegaer aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited < 2important.  
 vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.  
 autopoll selfing pollination, an ordered factor with levels 0never < 1rare < 2 often < the rule3  
 insects insect pollination, an ordered factor with 5 levels 0 < ... < 4.  
 wind wind pollination, an ordered factor with 5 levels 0 < ... < 4.  
 lign a binary factor with levels 0:1, indicating if plant is woody.  
 piq a binary factor indicating if plant is thorny.  
 ros a binary factor indicating if plant is rosette.  
 semiros semi-rosette plant, a binary factor (0: no; 1: yes).  
 leafy leafy plant, a binary factor.  
 suman summer annual, a binary factor.  
 winan winter annual, a binary factor.  
 monocarp monocarpic perennial, a binary factor.  
 polycarp polycarpic perennial, a binary factor.  
 seasaes seasonal aestival leaves, a binary factor.  
 seashiv seasonal hibernal leaves, a binary factor.  
 seasver seasonal vernal leaves, a binary factor.  
 everalw leaves always evergreen, a binary factor.  
 everparti leaves partially evergreen, a binary factor.  
 elaio fruits with an elaiosome (dispersed by ants), a binary factor.  
 endozoo endozoochorous fruits, a binary factor.  
 epizoo epizoochorous fruits, a binary factor.  
 aquat aquatic dispersal fruits, a binary factor.  
 windgl wind dispersed fruits, a binary factor.  
 unsp unspecialized mechanism of seed dispersal, a binary factor.

**Details**

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

## Examples

```
data(plantTraits)

## Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
              type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis
cmds dai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

---

plot.agnes

*Plots of an Agglomerative Hierarchical Clustering*

---

## Description

Creates plots for visualizing an `agnes` object.

## Usage

```
## S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

## Arguments

<code>x</code>	an object of class "agnes", typically created by <code>agnes()</code> .
<code>ask</code>	logical; if true and <code>which.plots</code> is NULL, <code>plot.agnes</code> operates in interactive mode, via <code>menu</code> .
<code>which.plots</code>	integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”.
<code>main</code> , <code>sub</code>	main and sub title for the plot, with convenient defaults. See documentation for these arguments in <code>plot.default</code> .
<code>adj</code>	for label adjustment in <code>bannerplot()</code> .

<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in banner plot labeling.
<code>xax.pretty</code>	logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.
<code>...</code>	graphical parameters (see <code>par</code> ) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> (see <code>pltree.twins</code> ), respectively.

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the `agnes` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree()`, i.e., its method `pltree.twins`, respectively.

directly with corresponding arguments, e.g., `xlab` or `ylab`.

## Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For the dendrogram, more flexibility than via `pltree()` is provided by `dg <- as.dendrogram(x)` and plotting `dg` via `plot.dendrogram`.

## Can also pass `labels' to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "G"
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150) # bannerplot labels are mess
```

---

plot.diana

---

*Plots of a Divisive Hierarchical Clustering*

---

**Description**

Creates plots for visualizing a diana object.

**Usage**

```
## S3 method for class 'diana'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
      sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
      adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

**Arguments**

<code>x</code>	an object of class "diana", typically created by <a href="#">diana(.)</a> .
<code>ask</code>	logical; if true and <code>which.plots</code> is NULL, <code>plot.diana</code> operates in interactive mode, via <a href="#">menu</a> .
<code>which.plots</code>	integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”.
<code>main, sub</code>	main and sub title for the plot, each with a convenient default. See documentation for these arguments in <a href="#">plot.default</a> .
<code>adj</code>	for label adjustment in <a href="#">bannerplot()</a> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in banner plot labeling.
<code>xax.pretty</code>	logical or integer indicating if <a href="#">pretty(*, n = xax.pretty)</a> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.
<code>...</code>	graphical parameters (see <a href="#">par</a> ) may also be supplied and are passed to <a href="#">bannerplot()</a> or <a href="#">pltree()</a> , respectively.

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.diana` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the `diana` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

## Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

## References

see those in `plot.agnes`.

## See Also

`diana`, `diana.object`, `twins.object`, `par`.

## Examples

```
example(diana) # -> dv <- diana(...)

plot(dv, which = 1, nmax.lab = 100)

## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0, 0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
```

## Description

Creates the banner of a `mona` object.

**Usage**

```
## S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse(x$call)),
      sub = NULL, xlab = "Separation step",
      col = c(2,0), axes = TRUE, adj = 0,
      nmax.lab = 35, max.strlen = 5, ...)
```

**Arguments**

<code>x</code>	an object of class "mona", typically created by <code>mona(.)</code> .
<code>main, sub</code>	main and sub titles for the plot, with convenient defaults. See documentation in <code>plot.default</code> .
<code>xlab</code>	x axis label, see <code>title</code> .
<code>col, adj</code>	graphical parameters passed to <code>bannerplot()</code> .
<code>axes</code>	logical, indicating if (labeled) axes should be drawn.
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for labeling.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in labeling.
<code>...</code>	further graphical arguments are passed to <code>bannerplot()</code> and <code>text</code> .

**Details**

Plots the separation step at which clusters are splitted. The observations are given in the order found by the `mona` algorithm, the numbers in the `step` vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

**Side Effects**

A banner is plotted on the current graphics device.

**Note**

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

**References**

see those in `plot.agnes`.

**See Also**

`mona`, `mona.object`, `par`.

---

plot.partition      *Plot of a Partition of the Data Set*

---

## Description

Creates plots for visualizing a `partition` object.

## Usage

```
## S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
     nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
     stand = FALSE, lines = 2,
     shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
     span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

## Arguments

<code>x</code>	an object of class "partition", typically created by the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .
<code>ask</code>	logical; if true and <code>which.plots</code> is NULL, <code>plot.partition</code> operates in interactive mode, via <a href="#">menu</a> .
<code>which.plots</code>	integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>clusplot</i> or 2 for <i>silhouette</i> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in silhouette plot labeling.
<code>data</code>	numeric matrix with the scaled data; per default taken from the partition object <code>x</code> , but can be specified explicitly.
<code>dist</code>	when <code>x</code> does not have a <code>diss</code> component as for <a href="#">pam</a> (*, keep.diss=FALSE), <code>dist</code> must be the dissimilarity if a <i>clusplot</i> is desired.
<code>stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...</code>	All optional arguments available for the <a href="#">clusplot.default</a> function (except for the <code>diss</code> one) and graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.

## Details

When `ask= TRUE`, rather than producing each plot sequentially, `plot.partition` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask= TRUE)` before invoking the plot command.

The *clusplot* of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see [clusplot.partition](#) for more details).

The *silhouette plot* of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation *i*, a bar is drawn, representing its silhouette width *s(i)*, see [silhouette](#) for details. Observations are grouped per cluster, starting

with cluster 1 at the top. Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

A clustering can be performed for several values of  $k$  (the number of clusters). Finally, choose the value of  $k$  with the largest overall average silhouette width.

### Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot

Silhouette plot

### Note

In the silhouette plot, observation labels are only printed when the number of observations is less than `nmax.lab` (40, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see [plot.silhouette](#).

### References

Rousseeuw, P.J. (1987) Silhouettes: A graphical aid to the interpretation and validation of cluster analysis. *J. Comput. Appl. Math.*, **20**, 53–65.

Further, the references in [plot.agnes](#).

### See Also

[partition.object](#), [clusplot.partition](#), [clusplot.default](#), [pam](#),  
[pam.object](#), [clara](#), [clara.object](#), [fanny](#), [fanny.object](#), [par](#).

### Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

### Description

`pltree()` Draws a clustering tree (“dendrogram”) on the current graphics device. We provide the `twins` method draws the tree of a `twins` object, i.e., hierarchical clustering, typically resulting from [agnes\(\)](#) or [diana\(\)](#).

## Usage

```
ptree(x, ...)
## S3 method for class 'twins'
ptree(x, main = paste("Dendrogram of ", deparse(x$call)),
      labels = NULL, ylab = "Height", ...)
```

## Arguments

<code>x</code>	in general, an R object for which a <code>ptree</code> method is defined; specifically, an object of class "twins", typically created by either <code>agnes()</code> or <code>diana()</code> .
<code>main</code>	main title with a sensible default.
<code>labels</code>	labels to use; the default is constructed from <code>x</code> .
<code>ylab</code>	label for y-axis.
<code>...</code>	graphical parameters (see <code>par</code> ) may also be supplied as arguments to this function.

## Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(..)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

## Value

a NULL value is returned.

## See Also

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

## Examples

```
data(votes.repub)
agn <- agnes(votes.repub)
ptree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
      nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
      main = deparse(agn$call))
par(op)
```

---

 pluton

---

*Isotopic Composition Plutonium Batches*

---

## Description

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

## Usage

```
data(pluton)
```

## Format

This data frame contains the following columns:

**Pu238** the percentages of  $^{238}\text{Pu}$ , always less than 2 percent.

**Pu239** the percentages of  $^{239}\text{Pu}$ , typically between 60 and 80 percent (from neutron capture of Uranium,  $^{238}\text{U}$ ).

**Pu240** percentage of the plutonium 240 isotope.

**Pu241** percentage of the plutonium 241 isotope.

## Details

Note that the percentage of plutonium~242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

## Source

Available as ‘`pluton.dat`’ from the archive of the University of Antwerpen,  
 ‘`../datasets/clusplot-examples.tar.gz`’, no longer available.

## References

Rousseeuw, P.J. and Kaufman, L and Trauwaert, E. (1996) Fuzzy clustering using scatter matrices, *Computational Statistics and Data Analysis* **23**(1), 135–151.

## Examples

```
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

---

predict.ellipsoid *Predict Method for Ellipsoid Objects*

---

## Description

Compute points on the ellipsoid boundary, mostly for drawing.

## Usage

```
predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)
```

## Arguments

object	an object of class <code>ellipsoid</code> , typically from <code>ellipsoidhull()</code> ; alternatively any list-like object with proper components, see details below.
n.out, n.half	half the number of points to create.
A, d2, loc	arguments of the auxiliary <code>ellipsoidPoints</code> , see below.
...	passed to and from methods.

## Details

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see `ellipsoidhull`. The class of object is not checked; it must solely have valid components `loc` (length  $p$ ), the  $p \times p$  matrix `cov` (corresponding to A) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq(*, p)` quantile.

Unfortunately, this is only implemented for  $p = 2$ , currently; contributions for  $p \geq 3$  are *very welcome*.

## Value

a numeric matrix of dimension  $2 \times n.out$  times  $p$ .

## See Also

`ellipsoidhull`, `volume.ellipsoid`.

## Examples

```
## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)")
mtext("with classical and robust cov.matrix ellipsoids")
```

```

X <- cbind(x,y)
C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
  Cxy <- cov.rob(cbind(x,y))
  lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
}# MASS

```

---

print.agnes

*Print Method for AGNES Objects*

---

### Description

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an `agnes` object.

This is a method for the generic `print()` function for objects inheriting from class `agnes`, see `agnes.object`.

### Usage

```
## S3 method for class 'agnes'
print(x, ...)
```

### Arguments

`x` an `agnes` object.  
`...` potential further arguments (required by generic).

### See Also

`summary.agnes` producing more output; `agnes`, `agnes.object`, `print`, `print.default`.

---

print.clara

*Print Method for CLARA Objects*

---

### Description

Prints the best sample, medoids, clustering vector and objective function of `clara` object.

This is a method for the function `print()` for objects inheriting from class `clara`.

### Usage

```
## S3 method for class 'clara'
print(x, ...)
```

**Arguments**

`x` a clara object.  
`...` potential further arguments (require by generic).

**See Also**

`summary.clara` producing more output; `clara`, `clara.object`, `print`, `print.default`.

---

print.diana	<i>Print Method for DIANA Objects</i>
-------------	---------------------------------------

---

**Description**

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object.

This is a method for the function `print()` for objects inheriting from class `diana`.

**Usage**

```
## S3 method for class 'diana'
print(x, ...)
```

**Arguments**

`x` a diana object.  
`...` potential further arguments (require by generic).

**See Also**

`diana`, `diana.object`, `print`, `print.default`.

---

print.dissimilarity	<i>Print and Summary Methods for Dissimilarity Objects</i>
---------------------	--

---

**Description**

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions `print()` and `summary()` for dissimilarity objects. See `print`, `print.default`, or `summary` for the general behavior of these.

**Usage**

```
## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity'
summary(object,
        digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity'
print(x, ...)
```

**Arguments**

`x, object` a dissimilarity object or a `summary.dissimilarity` one for `print.summary.dissimilarity()`.

`digits` the number of digits to use, see [print.default](#).

`diag, upper, justify, right` optional arguments specifying how the triangular dissimilarity matrix is printed; see [print.dist](#).

`...` potential further arguments (require by generic).

**See Also**

[daisy](#), [dissimilarity.object](#), [print](#), [print.default](#), [print.dist](#).

**Examples**

```
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```

---

print.fanny

---

*Print and Summary Methods for FANNY Objects*

---

**Description**

Prints the objective function, membership coefficients and clustering vector of `fanny` object.

This is a method for the function [print\(\)](#) for objects inheriting from class [fanny](#).

**Usage**

```
## S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny'
summary(object, ...)
## S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)
```

**Arguments**

`x, object` a [fanny](#) object.  
`digits` number of significant digits for printing, see [print.default](#).  
`...` potential further arguments (required by generic).

**See Also**

[fanny](#), [fanny.object](#), [print](#), [print.default](#).

---

`print.mona`

*Print Method for MONA Objects*

---

**Description**

Prints the ordering of objects, separation steps, and used variables of a `mona` object.  
This is a method for the function [print](#) () for objects inheriting from class [mona](#).

**Usage**

```
## S3 method for class 'mona'
print(x, ...)
```

**Arguments**

`x` a `mona` object.  
`...` potential further arguments (require by generic).

**See Also**

[mona](#), [mona.object](#), [print](#), [print.default](#).

---

`print.pam`

*Print Method for PAM Objects*

---

**Description**

Prints the medoids, clustering vector and objective function of `pam` object.  
This is a method for the function [print](#) () for objects inheriting from class [pam](#).

**Usage**

```
## S3 method for class 'pam'
print(x, ...)
```

**Arguments**

`x` a `pam` object.  
`...` potential further arguments (require by generic).

**See Also**

[pam](#), [pam.object](#), [print](#), [print.default](#).

---

ruspini

*Ruspini Data*

---

**Description**

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

**Usage**

```
data(ruspini)
```

**Format**

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

**Source**

E. H. Ruspini (1970) Numerical methods for fuzzy clustering. *Inform. Sci.* **2**, 319–350.

**References**

see those in [agnes](#).

**Examples**

```
data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

silhouette

*Compute or Extract Silhouette Information from Clustering***Description**

Compute silhouette information according to a given clustering in  $k$  clusters.

**Usage**

```
silhouette(x, ...)
## Default S3 method:
  silhouette(x, dist, dmatrix, ...)
## S3 method for class 'partition'
silhouette(x, ...)
## S3 method for class 'clara'
silhouette(x, full = FALSE, ...)

sortSilhouette(object, ...)
## S3 method for class 'silhouette'
summary(object, FUN = mean, ...)
## S3 method for class 'silhouette'
plot(x, nmax.lab = 40, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width " * s[i]),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)
```

**Arguments**

<code>x</code>	an object of appropriate class; for the default method an integer vector with $k$ different integer cluster codes or a list with such an <code>x\$clustering</code> component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$ .
<code>dist</code>	a dissimilarity object inheriting from class <code>dist</code> or coercible to one. If not specified, <code>dmatrix</code> must be.
<code>dmatrix</code>	a symmetric dissimilarity matrix ( $n \times n$ ), specified instead of <code>dist</code> , which can be more efficient.
<code>full</code>	logical specifying if a <i>full</i> silhouette should be computed for <code>clara</code> object. Note that this requires $O(n^2)$ memory, since the full dissimilarity (see <code>daisy</code> ) is needed internally.
<code>object</code>	an object of class <code>silhouette</code> .
<code>...</code>	further arguments passed to and from methods.
<code>FUN</code>	function used to summarize silhouette widths.
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in silhouette plot labeling.
<code>main, sub, xlab</code>	arguments to <code>title</code> ; have a sensible non-NULL default here.

`col`, `border`, `cex.names`  
arguments passed `barplot()`; note that the default used to be `col = heat.colors(n)`, `border = par("fg")` instead.  
`col` can also be a color vector of length  $k$  for clusterwise coloring, see also `do.col.sort`:  
`do.col.sort` logical indicating if the colors `col` should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.  
`do.n.k` logical indicating if  $n$  and  $k$  “title text” should be written.  
`do.clus.stat` logical indicating if cluster size and averages should be written right to the silhouettes.

## Details

For each observation  $i$ , the *silhouette width*  $s(i)$  is defined as follows:

Put  $a(i)$  = average dissimilarity between  $i$  and all other points of the cluster to which  $i$  belongs (if  $i$  is the *only* observation in its cluster,  $s(i) := 0$  without further calculations). For all *other* clusters  $C$ , put  $d(i, C)$  = average dissimilarity of  $i$  to all observations of  $C$ . The smallest of these  $d(i, C)$  is  $b(i) := \min_C d(i, C)$ , and can be seen as the dissimilarity between  $i$  and its “neighbor” cluster, i.e., the nearest one to which it does *not* belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.$$

`silhouette.default()` is now based on C code donated by Romain Francois (the R version being still available as `cluster::silhouette.default.R`).

Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

## Value

`silhouette()` returns an object, `sil`, of class `silhouette` which is an  $[n \times 3]$  matrix with attributes. For each observation  $i$ , `sil[i, ]` contains the cluster to which  $i$  belongs as well as the neighbor cluster of  $i$  (the cluster, not containing  $i$ , for which the average dissimilarity between its observations and  $i$  is minimal), and the silhouette width  $s(i)$  of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

`summary(sil)` returns an object of class `summary.silhouette`, a list with components

`si.summary` numerical `summary` of the individual silhouette widths  $s(i)$ .  
`clus.avg.widths` numeric (rank 1) array of clusterwise *means* of silhouette widths where `mean = FUN` is used.  
`avg.width` the total mean `FUN(s)` where  $s$  are the individual silhouette widths.  
`clus.sizes` `table` of the  $k$  cluster sizes.  
`call` if available, the call creating `sil`.  
`Ordered` logical identical to `attr(sil, "Ordered")`, see below.

`sortSilhouette(sil)` orders the rows of `sil` as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width  $s(i)$ .

`attr(sil, "Ordered")` is a logical indicating if `sil` is ordered as by `sortSilhouette()`. In that case, `rownames(sil)` will contain case labels or numbers, and

`attr(sil, "iOrd")` the ordering index vector.

**Note**

While `silhouette()` is *intrinsic* to the `partition` clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from `silhouette.default()` with `cutree()` and distance as input.

By default, for `clara()` partitions, the silhouette is just for the best random *subset* used. Use `full = TRUE` to compute (and later possibly plot) the full silhouette.

chapter 2 of Kaufman and Rousseeuw (1990), see the references in `plot.agnes`.

**See Also**

`partition.object`, `plot.partition`.

**Examples**

```
data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple")) # with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
          mgp= c(1.6, .8, 0), mar= .1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
      outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

## the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE,
       col = c6[1:k])
par(op)

## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xclk <- xclara[sample(nrow(xclara), size = 1000) ,])
cl3 <- clara(xclk, 3)
plot(silhouette(cl3)) # only of the "best" subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE) ## this is the same as
s.full <- silhouette(cl3$clustering, daisy(xclk))
if(paste(R.version$major, R.version$minor, sep=".") >= "2.3.0")
  stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tolerance = 0))
```

```
## color dependent on original "3 groups of each 1000":
plot(sf, col = 2+ as.integer(names(cl3$clustering) ) %% 1000,
     main ="plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
                 daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)
```

sizeDiss

*Sample Size of Dissimilarity Like Object***Description**

Returns the number of observations (*sample size*) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of  $f(n) = n(n-1)/2$ .

**Usage**

```
sizeDiss(d)
```

**Arguments**

d                      any R object with length (typically)  $n(n-1)/2$ .

**Value**

a number;  $n$  if `length(d) == n(n-1)/2`, NA otherwise.

**See Also**

`dissimilarity.object` and also `as.dist` for class dissimilarity and dist objects which have a `Size` attribute.

**Examples**

```
sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply( n*(n-1)/2, function(n) sizeDiss(logical(n))))
```

---

summary.agnes	<i>Summary Method for 'agnes' Objects</i>
---------------	---

---

### Description

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

### Usage

```
## S3 method for class 'agnes'
summary(object, ...)
## S3 method for class 'summary.agnes'
print(x, ...)
```

### Arguments

`x, object`      a `agnes` object.  
`...`            potential further arguments (require by generic).

### See Also

`agnes`, `agnes.object`.

### Examples

```
data(agriculture)
summary(agnes(agriculture))
```

---

summary.clara	<i>Summary Method for 'clara' Objects</i>
---------------	---

---

### Description

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

### Usage

```
## S3 method for class 'clara'
summary(object, ...)
## S3 method for class 'summary.clara'
print(x, ...)
```

### Arguments

`x, object`      a `clara` object.  
`...`            potential further arguments (require by generic).

**See Also**

[clara.object](#)

**Examples**

```
## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0,4), rnorm(400, 0,4)),
           cbind(rnorm(400,10,8), rnorm(400,40,6)),
           cbind(rnorm(400,30,4), rnorm(400, 0,4)),
           cbind(rnorm(400,40,4), rnorm(400,20,2)),
           cbind(rnorm(400,50,4), rnorm(400,50,4))
)
clx5 <- clara(x, 5)
## Mis`classification' table:

table(rep(1:5, rep(400,5)), clx5$clust) # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3,1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0,0,2,0))

plot(x, col = rep(2:6, rep(400,5)))
plot(clx5)
```

---

summary.diana

*Summary Method for 'diana' Objects*

---

**Description**

Returns (and prints) a summary list for a diana object.

**Usage**

```
## S3 method for class 'diana'
summary(object, ...)
## S3 method for class 'summary.diana'
print(x, ...)
```

**Arguments**

**x, object**      a [diana](#) object.

**...**            potential further arguments (require by generic).

**See Also**

[diana](#), [diana.object](#).

---

summary.mona*Summary Method for 'mona' Objects*

---

**Description**

Returns (and prints) a summary list for a mona object.

**Usage**

```
## S3 method for class 'mona'
summary(object, ...)
## S3 method for class 'summary.mona'
print(x, ...)
```

**Arguments**

`x, object`      a mona object.  
`...`            potential further arguments (require by generic).

**See Also**

[mona](#), [mona.object](#).

---

summary.pam*Summary Method for PAM Objects*

---

**Description**

Summarize a pam object and return an object of class summary.pam. There's a [print](#) method for the latter.

**Usage**

```
## S3 method for class 'pam'
summary(object, ...)
## S3 method for class 'summary.pam'
print(x, ...)
```

**Arguments**

`x, object`      a pam object.  
`...`            potential further arguments (require by generic).

**See Also**

[pam](#), [pam.object](#).

---

twins.object	<i>Hierarchical Clustering Object</i>
--------------	---------------------------------------

---

### Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

### Value

See [agnes.object](#) and [diana.object](#) for details.

### GENERATION

This class of objects is returned from `agnes` or `diana`.

### METHODS

The "twins" class has a method for the following generic function: `pltree`.

### INHERITANCE

The following classes inherit from class "twins": "agnes" and "diana".

### See Also

[agnes](#), [diana](#).

---

volume.ellipsoid	<i>Compute the Volume of Planar Object</i>
------------------	--

---

### Description

Compute the volume of a planar object. This is a generic function and a method for `ellipsoid` objects.

### Usage

```
## S3 method for class 'ellipsoid'
volume(object)
```

### Arguments

object	an R object the volume of which is wanted; for the <code>ellipsoid</code> method, an object of that class (see <a href="#">ellipsoidhull</a> or the example below).
--------	---

### Value

a number, the volume of the given object.

**See Also**

`ellipsoidhull` for spanning ellipsoid computation.

**Examples**

```
## example(ellipsoidhull) # which defines `ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
                    class = "ellipsoid")
volume(myEl) # i.e. "area" here (d = 2)
myEl # also mentions the "volume"
```

---

votes.repub

*Votes for Republican Candidate in Presidential Elections*

---

**Description**

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

**Usage**

```
data(votes.repub)
```

**Source**

S. Peterson (1973): *A Statistical History of the American Presidential Elections*. New York: Frederick Ungar Publishing Co.

Data from 1964 to 1976 is from R. M. Scammon, *American Votes 12*, Congressional Quarterly.

---

xclara

*Bivariate Data Set with 3 Clusters*

---

**Description**

An artificial data set consisting of 3000 points in 3 well-separated clusters of size 1000 each.

**Usage**

```
data(xclara)
```

**Format**

A data frame with 3000 observations on 2 numeric variables giving the  $x$  and  $y$  coordinates of the points, respectively.

**Source**

Sample data set accompanying the reference below.

**References**

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996) Clustering in an Object-Oriented Environment. *Journal of Statistical Software* **1**. <http://www.jstatsoft.org/v01/i04>

## Chapter 21

# The codetools package

---

checkUsage

*Check R Code for Possible Problems*

---

### Description

Check R code for possible problems.

### Usage

```
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
            suppressLocal = FALSE, suppressParamAssigns = !all,
            suppressParamUnused = !all, suppressFundefMismatch = FALSE,
            suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
            skipWith = FALSE, suppressUndefined = dfltSuppressUndefined,
            suppressPartialMatchArgs = TRUE)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

### Arguments

fun	closure.
name	character; name of closure.
env	environment containing closures to check.
pack	character naming package to check.
...	options to be passed to checkUsage.
report	function to use to report possible problems.
all	logical; report all possible problems if TRUE.
suppressLocal	suppress all local variable warnings.
suppressParamAssigns	suppress warnings about assignments to formal parameters.
suppressParamUnused	suppress warnings about unused formal parameters.

```
suppressFundefMismatch
    suppress warnings about multiple local function definitions with different formal
    argument lists
suppressLocalUnused
    suppress warnings about unused local variables
suppressNoLocalFun
    suppress warnings about using local variables as functions with no apparent
    local function definition
skipWith      logical; if true, do not examine code portion of with expressions.
suppressUndefined
    suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
    suppress warnings about partial argument matching
```

### Details

`checkUsage` checks a single R closure. Options control which possible problems to report. The default settings are moderately verbose. A first pass might use `suppressLocal=TRUE` to suppress all information related to local variable usage. The `suppressXYZ` values can either be scalar logicals or character vectors; then they are character vectors they only suppress problem reports for the variables with names in the vector.

`checkUsageEnv` and `checkUsagePackage` are convenience functions that apply `checkUsage` to all closures in an environment or a package. `checkUsagePackage` requires that the package be loaded. If the package has a name space then the internal name space frame is checked.

### Author(s)

Luke Tierney

### Examples

```
checkUsage(checkUsage)
checkUsagePackage("codetools", all=TRUE)
## Not run: checkUsagePackage("base", suppressLocal=TRUE)
```

### Description

These functions provide some tools for analysing R code. Mainly indented to support the other tools in this package and byte code compilation.

**Usage**

```

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)
findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
                    startCollectLocals, finishCollectLocals, warn,
                    signal)
walkCode(e, w = makeCodeWalker())

```

**Arguments**

<code>e</code>	R expression.
<code>elist</code>	list of R expressions.
<code>v</code>	R object.
<code>fun</code>	closure.
<code>formals</code>	formal arguments of a closure.
<code>body</code>	body of a closure.
<code>name</code>	character.
<code>env</code>	character.
<code>envir</code>	environment.
<code>w</code>	code walker.
<code>...</code>	extra elements for code walker.
<code>collect</code>	function.
<code>fail</code>	function.
<code>handler</code>	function.
<code>call</code>	function.
<code>leaf</code>	function.
<code>isLocal</code>	function.
<code>exit</code>	function.
<code>enterLocal</code>	function.
<code>enterGlobal</code>	function.
<code>enterInternal</code>	function.
<code>startCollectLocals</code>	function.
<code>finishCollectLocals</code>	function.
<code>warn</code>	function.
<code>signal</code>	function.

**Author(s)**

Luke Tierney

---

`findGlobals`*Find Global Functions and Variables Used by a Closure*

---

**Description**

Finds global functions and variables used by a closure.

**Usage**

```
findGlobals(fun, merge = TRUE)
```

**Arguments**

<code>fun</code>	closure.
<code>merge</code>	logical

**Details**

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of `assign` and `rm`).

**Value**

Character vector if `merge` is true; otherwise, a list with `functions` and `variables` components.

**Author(s)**

Luke Tierney

**Examples**

```
findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
```

---

showTree*Print Lisp-Style Representation of R Expression*

---

**Description**

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

**Usage**

```
showTree(e, write = cat)
```

**Arguments**

e	R expression.
write	function of one argument to write the result.

**Author(s)**

Luke Tierney

**Examples**

```
showTree(quote(-3))
showTree(quote("x"<-1))
showTree(quote("f"(x)))
```

## Chapter 22

# The foreign package

---

`lookup.xport`

*Lookup Information on a SAS XPORT Format Library*

---

### Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

### Usage

```
lookup.xport (file)
```

### Arguments

<code>file</code>	character variable with the name of the file to read. The file must be in SAS XPORT format.
-------------------	---

### Value

A list with one component for each dataset in the XPORT format library.

### Author(s)

Saikat DebRoy

### References

SAS Technical Support document TS-140: “The Record Layout of a Data Set in SAS Transport (XPORT) Format” available as <https://support.sas.com/techsup/technote/ts140.pdf>.

### See Also

**Examples**

```
## Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

## End(Not run)
```

---

read.arff

*Read Data from ARFF Files*

---

**Description**

Reads data from Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```
read.arff(file)
```

**Arguments**

`file` a character string with the name of the ARFF file to read from, or a [connection](#) which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A data frame containing the data from the ARFF file.

**References**

Attribute-Relation File Format <http://www.cs.waikato.ac.nz/~ml/weka/arff.html>  
<http://sourceforge.net/projects/weka/files/documentation/>.

**See Also**

[write.arff](#)

---

read.dbf

*Read a DBF File*

---

**Description**

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

**Usage**

```
read.dbf(file, as.is = FALSE)
```

## Arguments

<code>file</code>	name of input file
<code>as.is</code>	should character vectors not be converted to factors?

## Details

DBF is the extension used for files written for the 'XBASE' family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' (<http://www.clicketyclick.dk/databases/xbase/format/>). Most of these follow the file structure used by Ashton-Tate's dBase II, III or 4 (later owned by Borland).

`read.dbf` is based on C code from <http://shapelib.maptools.org/> which implements the 'XBASE' specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that it is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

## Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names(unique=TRUE)`.

There is an attribute "data\_type" giving the single-character dBase types for each field.

## Note

Not to be able to read a particular 'DBF' file is not a bug: this is a convenience function especially for shapefiles.

## Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

## References

## Examples

```
x <- read.dbf(system.file("files/sids.dbf", package="foreign"))[1]
str(x)
summary(x)
```

read.dta

*Read Stata Binary Files***Description**

Reads a file in Stata version 5–12 binary format into a data frame.

Frozen: will not support Stata formats after 12.

**Usage**

```
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
         missing.type = FALSE,
         convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

`file` a filename or URL as a character string.

`convert.dates` Convert Stata dates to Date class, and date-times to POSIXct class?

`convert.factors` Use Stata value labels to create factors? (Version 6.0 or later).

`missing.type` For version 8 or later, store information about different types of missing data?

`convert.underscore` Convert "\_" in Stata variable names to "." in R names?

`warn.missing.labels` Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R's Date class, and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata's date formats are sketchily documented: if necessary use `convert.dates = FALSE` and examine the attributes to work out how to post-process the dates.

Stata 8 introduced a system of 27 different missing data values. If `missing.type` is TRUE a separate list is created with the same variable names as the loaded data. For string variables the list value is NULL. For other variables the value is NA where the observation is not missing and 0–26 when the observation is missing. This is attached as the "missing" attribute of the returned value.

The default file format for Stata 13, `format-115`, is substantially different from those for Stata 5–12.

**Value**

A data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table" and "expansion.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, 'format-111'), 8 (Stata 8 and 9, 'format-113'), 10 (Stata 10 and 11, 'format-114'), and 12 (Stata 12, 'format-115').

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names.

**Author(s)**

Thomas Lumley and R-core members: support for value labels by Brian Quistorff.

write.dta(swiss,swissfile <- tempfile())
read.dta(swissfile)
```

---

`read.epiinfo`*Read Epi Info Data Files*

---

**Description**

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

**Usage**

```
read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE,
             thisyear = NULL, lower.case.names = FALSE)
```

## Arguments

`file` A filename, URL, or connection.

`read.deleted` Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.

`guess.broken.dates` Attempt to convert dates with 0 or 2 digit year information (see 'Details').

`thisyear` A 4-digit year to use for dates with no year. Defaults to the current year.

`lower.case.names` Convert variable names to lowercase?

## Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to `Date` class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system's default method (see [Date](#)) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is TRUE the "deleted" attribute of the data frame indicates the deleted records.

## Value

A data frame.

## Note

Some later versions of Epi Info use the Microsoft Access file format to store data. That may be readable with the **RODBC** package.

## References

<http://www.cdc.gov/epiinfo/>, <http://www.epidata.dk>

## See Also

[DateTimeClasses](#)

## Examples

```
## Not run: ## That file is not available
read.epiinfo("oswego.rec", guess.broken.dates = TRUE, thisyear = "1972")

## End(Not run)
```

---

`read.mtp`*Read a Minitab Portable Worksheet*

---

## Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

## Usage

```
read.mtp(file)
```

## Arguments

<code>file</code>	character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.
-------------------	--

## Value

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

## Note

This function was written around 1990 for the format current then. Later versions of Minitab appear to have added to the format.

## Author(s)

Douglas M. Bates

## References

<http://www.minitab.com/>

## Examples

```
## Not run:  
read.mtp("ex1-10.mtp")  
  
## End (Not run)
```

---

`read.octave`*Read Octave Text Data Files*

---

**Description**

Read a file in Octave text data format into a list.

**Usage**

```
read.octave(file)
```

**Arguments**

`file`                    a character string with the name of the file to read.

**Details**

This function is used to read in files in Octave text data format, as created by `save -text` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and  $N$ -d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and `NULL` is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave's load and save (as text) facilities as an intermediary step.

**Value**

A list with one named component for each variable in the file.

**Author(s)**

Stephen Eglen <stephen@gnu.org> and Kurt Hornik

**References**

<http://www.octave.org/>

---

`read.spss`*Read an SPSS Data File*

---

**Description**

`read.spss` reads a file stored by the SPSS `save` or `export` commands.

This was originally written in 2000 and has limited support for changes in SPSS formats since (which have not been many).

## Usage

```
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,
          max.value.labels = Inf, trim.factor.names = FALSE,
          trim_values = TRUE, reencode = NA, use.missings = to.data.frame)
```

## Arguments

<code>file</code>	character string: the name of the file or URL to read.
<code>use.value.labels</code>	logical: convert variables with value labels into R factors with those levels? This is only done if there are at least as many labels as values of the variable (when values without a matching label are returned as NA).
<code>to.data.frame</code>	logical: return a data frame?
<code>max.value.labels</code>	logical: only variables with value labels and at most this many unique values will be converted to factors if TRUE.
<code>trim.factor.names</code>	logical: trim trailing spaces from factor levels?
<code>trim_values</code>	logical: should values and value labels have trailing spaces ignored when matching for <code>use.value.labels = TRUE</code> ?
<code>reencode</code>	logical: should character strings be re-encoded to the current locale. The default, NA, means to do so in a UTF-8 locale, only. Alternatively a character string specifying an encoding to assume for the file.
<code>use.missings</code>	logical: should information on user-defined missing values be used to set the corresponding values to NA?

## Details

This uses modified code from the PSPP project (<http://www.gnu.org/software/pspp/> for reading the SPSS formats.

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is supported where supported by [download.file](#) with its current default method.)

Occasionally in SPSS, value labels will be added to some values of a continuous variable (e.g. to distinguish different types of missing data), and you will not want these variables converted to factors. By setting `max.value.labels` you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels. In addition, variables will not be converted to factors if there are non-missing values that have no value label. The value labels are then returned in the "value.labels" attribute of the variable.

If SPSS variable labels are present, they are returned as the "variable.labels" attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument `trim_values=TRUE` causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for [sub](#) for ways to remove trailing spaces in character data.

URL [http://msdn.microsoft.com/en-us/library/ms776446\(VS.85\).aspx](http://msdn.microsoft.com/en-us/library/ms776446(VS.85).aspx) provides a list of translations from Windows codepage numbers to encoding names that [iconv](#) is

likely to know about and so suitable values for `reencode`. Automatic re-encoding is attempted for apparent codepages of 200 or more in a UTF-8 locale: some other high-numbered codepages can be re-encoded on most systems, but the encoding names are platform-dependent (see [iconvlist](#)).

### Value

A list (or optionally a data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute `"codepage"` to the result.

There may be attributes `"label.table"` and `"variable.labels"`. Attribute `"label.table"` is a named list of value labels with one element per variable, either `NULL` or a named character vector. Attribute `"variable.labels"` is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute `"Missings"`. This is a named list with one list element per variable. Each element has an element `type`, a length-one character vector giving the type of missingness, and may also have an element `value` with the values corresponding to missingness. This is a complex subject (where the R and C source code for `read.spss` is the main documentation), but the simplest cases are types `"one"`, `"two"` and `"three"` with a corresponding number of (real or string) values whose labels can be found from the `"label.table"` attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also [http://www.gnu.org/software/pspp/manual/html\\_node/Missing-Observations.html#Missing-Observations](http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations).

### Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1, 2, 3, ...

You may see warnings about the file encoding for SPSS `save` files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute `"codepage"` of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 locales: see argument `reencode`.

### Author(s)

Saikat DebRoy and the R-core team

### See Also

A different interface also based on the PSPP codebase is available in package **memisc**: see its help for `spss.system.file`.

### Examples

```
## Not run: ## if you have an SPSS file called 'datafile':
read.spss("datafile")
## don't convert value labels to factor levels
read.spss("datafile", use.value.labels = FALSE)
## convert value labels to factors for variables with at most
## ten distinct values.
read.spss("datafile", max.value.labels = 10)

## End(Not run)
```

---

read.ssd	<i>Obtain a Data Frame from a SAS Permanent Dataset, via read.xport</i>
----------	---

---

## Description

Generates a SAS program to convert the ssd contents to SAS transport format and then uses read.xport to obtain a data frame.

## Usage

```
read.ssd(libname, sectionnames,
         tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")
```

## Arguments

libname	character string defining the SAS library (usually a directory reference)
sectionnames	character vector giving member names. These are files in the libname directory. They will usually have a .ssd0x or .sas7bdat extension, which should be omitted. Use of ASCII names of at most 8 characters is strongly recommended.
tmpXport	character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.
tmpProgLoc	character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.
sascmd	character string giving full path to SAS executable.

## Details

Creates a SAS program and runs it.

Error handling is primitive.

## Value

A data frame if all goes well, or NULL with warnings and some enduring side effects (log file for auditing)

## Note

**This requires SAS to be available.** If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as .csv, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

SAS requires section names to be no more than 8 characters. This is worked by the use of symbolic links: these are barely supported on Windows.

R> form90 <- read.ssd("trialdata", "form90")

## Or for a Windows example
sashome <- "/Program Files/SAS/SAS 9.1"
read.ssd(file.path(sashome, "core", "sashelp"), "retail",
          sascmd = file.path(sashome, "sas.exe"))

## End(Not run)
```

---

read.systat

---

*Obtain a Data Frame from a Systat File*

---

**Description**

`read.systat` reads a rectangular data file stored by the Systat `SAVE` command as (legacy) `*.sys` or more recently `*.syd` files.

**Usage**

```
read.systat(file, to.data.frame = TRUE)
```

**Arguments**

`file` character variable with the name of the file to read  
`to.data.frame` return a data frame (otherwise a list)

**Details**

The function only reads those Systat files that are rectangular data files (`mtype = 1`), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is `FALSE`, and in that case character variables are returned as is and filled up to 12 characters with blanks on the

right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute "comment". Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

### Value

A data frame (or list) with one component for each variable in the saved data set.

### Author(s)

Roger Bivand

### References

Systat Manual, 1987, 1989

Bivand, R. S. (1992) SYSTAT-compatible software for modelling spatial dependence among observations. *Computers and Geosciences* **18**, 951–963.

### Examples

```
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[1])
str(iris.s)
summary(iris.s)
```

---

read.xport

---

*Read a SAS XPORT Format Library*

---

### Description

Reads a file as a SAS XPORT format library and returns a list of data.frames.

### Usage

```
read.xport(file)
```

### Arguments

file	character variable with the name of the file to read. The file must be in SAS XPORT format.
------	---

### Value

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by .\_, .A to .Z by SAS) are mapped to R NA.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by ' ' or ' ': these are not treated as R missing values.

## Not run: ## no XPORT file is installed
read.xport("test.xpt")

## End(Not run)
```

---

S3 read functions    *Read an S3 Binary or data.dump File*

---

**Description**

Reads binary data files or `data.dump` files that were produced in S version 3.

**Usage**

```
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

**Arguments**

<code>file</code>	the filename of the S-PLUS <code>data.dump</code> or binary file.
<code>print</code>	whether to print the name of each object as read from the file.
<code>verbose</code>	whether to print the name of every subitem within each object.
<code>env</code>	environment within which to create the restored object(s).

**Details**

`read.S` can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.

`data.restore` can read a similar range of files produced by `data.dump` and for newer versions of S-PLUS, those from `data.dump(..., oldStyle=TRUE)`.

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

**Value**

For `read.S`, an R version of the S3 object.

For `data.restore`, the name of the file.

**Author(s)**

Duncan Murdoch

**Examples**

```
## if you have an S-PLUS _Data file containing 'myobj'
## Not run: read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)

## End(Not run)
```

---

write.arff

*Write Data into ARFF Files*

---

**Description**

Writes data into Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```
write.arff(x, file, eol = "\n", relation = deparse(substitute(x)))
```

**Arguments**

<code>x</code>	the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.
<code>file</code>	either a character string naming a file, or a connection. "" indicates output to the standard output connection.
<code>eol</code>	the character(s) to print at the end of each line (row).
<code>relation</code>	The name of the relation to be written in the file.

**Details**

`relation` will be passed through `make.names` before writing to the file, in an attempt to it them acceptable to Weka, and column names what do not start with an alphabetic character will have `X` prepended.

However, the references say that ARFF files are ASCII files, and that encoding is not enforced.

**Examples**

```
write.arff(iris, file = "")
```

---

write.dbf

*Write a DBF File*

---

**Description**

The function tries to write a data frame to a DBF file.

**Usage**

```
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

**Arguments**

dataframe	a data frame object.
file	a file name to be written to.
factor2char	logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.
max_nchar	The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

**Details**

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

**Value**

Invisible NULL.

**Note**

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

**Examples**

```
str(warpbreaks)
try1 <- paste(tempfile(), ".dbf", sep = "")
write.dbf(warpbreaks, try1, factor2char = FALSE)
in1 <- read.dbf(try1)
str(in1)
try2 <- paste(tempfile(), ".dbf", sep = "")
write.dbf(warpbreaks, try2, factor2char = TRUE)
in2 <- read.dbf(try2)
str(in2)
unlink(c(try1, try2))
```

---

write.dta

*Write Files in Stata Binary Format*

---

**Description**

Writes the data frame to file in the Stata binary format. Does not write array variables unless they can be [drop](#)-ed to a vector.

Frozen: will not support Stata formats after 10 (also used by Stata 11).

**Usage**

```
write.dta(dataframe, file, version = 7L,
          convert.dates = TRUE, tz = "GMT",
          convert.factors = c("labels", "string", "numeric", "codes"))
```

## Arguments

<code>dataframe</code>	a data frame.
<code>file</code>	character string giving filename.
<code>version</code>	integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8, 11 to 10.
<code>convert.dates</code>	logical: convert <code>Date</code> and <code>POSIXct</code> objects: see section ‘Dates’.
<code>tz</code>	timezone for date conversion.
<code>convert.factors</code>	how to handle factors.

## Details

The major difference between supported file formats in Stata versions is that version 7.0 and later allow 32-character variable names (5 and 6 were restricted to 8-character names). The `abbreviate` function is used to trim variable names to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique. Each version of Stata is claimed to be able to read all earlier formats.

The columns in the data frame become variables in the Stata data set. Missing values are handled correctly.

There are four options for handling factors. The default is to use Stata ‘value labels’ for the factor levels. With `convert.factors = "string"`, the factor levels are written as strings (the name of the value label is taken from the `"val.labels"` attribute if it exists or the variable name otherwise). With `convert.factors = "numeric"` the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, `convert.factors = "codes"` writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

If the `"label.table"` attribute contains value labels with names not already attached to a variable (not the variable name or name from `"val.labels"`) then these will be written out as well.

If the `"datalabel"` attribute contains a string, it is written out as the dataset label otherwise the dataset label is `"Written by R."`.

If the `"expansion.table"` attribute exists expansion fields are written. This attribute should contain a list where each element is string vector of length three. The first vector element contains the name of a variable or `"_dta"` (meaning the dataset). The second element contains the characteristic name. The third contains the associated data.

If the `"val.labels"` attribute contains a string vector with a string label for each variable then this is written as the variable labels. Otherwise the variable names are repeated as variable labels.

If the `"var.labels"` attribute contains a string vector with a string label for each variable then this is written as the variable labels. Otherwise the variable names are repeated as variable labels.

For Stata 8 or later use the default `version = 7` – the only advantage of Stata 8 format over 7 is that it can represent multiple different missing value types, and R doesn’t have them. Stata 10/11 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded. Up to 244 bytes are allowed in character data, and longer strings will be truncated with a warning.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than  $8.988e+307$  may be misinterpreted by Stata.

**Value**

NULL

**Dates**

Unless disabled by argument `convert.dates = FALSE`, R date and date-time objects (`POSIXt` classes) are converted into the Stata date format, the number of days since 1960-01-01. (For date-time objects this may lose information.) Stata can be told that these are dates by

```
format xdate %td;
```

It is possible to pass objects of class `POSIXct` to Stata to be treated as one of its versions of date-times. Stata uses the number of milliseconds since 1960-01-01, either excluding (format `%tc`) or counting (format `%tC`) leap seconds. So either an object of class `POSIXct` can be passed to Stata with `convert.dates = FALSE` and converted in Stata, or 315619200 should be added and then multiplied by 1000 before passing to `write.dta` and assigning format `%tc`. Stata's comments on the first route are at <http://www.stata.com/manuals13/ddatetime.pdf>, but at the time of writing were wrong: R uses POSIX conventions and hence does not count leap seconds.

read.dta(swissfile)
```

---

write.foreign

---

*Write Text Files and Code to Read Them*

---

**Description**

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

**Usage**

```
write.foreign(df, datafile, codefile,
              package = c("SPSS", "Stata", "SAS"), ...)
```

**Arguments**

<code>df</code>	A data frame
<code>datafile</code>	Name of file for data output
<code>codefile</code>	Name of file for code output
<code>package</code>	Name of package
<code>...</code>	Other arguments for the individual <code>writeForeign</code> functions

**Details**

The work for this function is done by `foreign::writeForeignStata`, `foreign::writeForeignSAS` and `foreign::writeForeignSPSS`. To add support for another package, eg Systat, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (`Date`, `dates`, `date`, and `POSIXt` classes) and logical vectors are also supported for SAS and characters are supported for SPSS.

For `package="SAS"` there are optional arguments `dataname = "rdata"` taking a string that will be the SAS data set name, `validvarname` taking either "V6" or "V7", and `libpath = NULL` taking a string that will be the directory where the target SAS dataset will be written when the generated SAS code been run.

**Value**

Invisible `NULL`.

**Author(s)**

Thomas Lumley and Stephen Weigand

**Examples**

```
## Not run:
datafile<-tempfile()
codefile<-tempfile()
write.foreign(esoph,datafile,codefile,package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)

## End(Not run)
```

## Chapter 23

# The `lattice` package

---

A\_01\_Lattice

*Lattice Graphics*

---

### Description

The **lattice** add-on package is an implementation of Trellis graphics for R. It is a powerful and elegant high-level data visualization system with an emphasis on multivariate data. It is designed to meet most typical graphics needs with minimal tuning, but can also be easily extended to handle most nonstandard requirements.

### Details

Trellis Graphics, originally developed for S and S-PLUS at the Bell Labs, is a framework for data visualization developed by R. A. Becker, W. S. Cleveland, et al, extending ideas presented in Cleveland's 1993 book *Visualizing Data*. The Lattice API is based on the original design in S, but extends it in many ways.

The Lattice user interface primarily consists of several 'high-level' generic functions (listed below in the "See Also" section), each designed to create a particular type of display by default. Although the functions produce different output, they share many common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`, which also includes a discussion of the important topics of *conditioning* and control of the Trellis layout. Features specific to other high-level functions are documented in their respective help pages.

Lattice employs an extensive system of user-controllable settings to determine the look and feel of the displays it produces. To learn how to use and customize the graphical parameters used by lattice, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are (potentially) different for different graphical devices. To learn how to initialize new devices with the desired settings or change the settings of the current device, see `trellis.device`.

It is usually unnecessary, but sometimes important to be able to plot multiple lattice plots on a single page. Such capabilities are described in the `print.trellis` help page. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment lattice plots after they are drawn (including *locator*-like functionality) are described in the `trellis.focus` help page.

The online documentation accompanying the package is complete, and effort has been made to present the help pages in a logical sequence, so that one can learn how to use lattice by reading the

PDF reference manual available at <http://cran.r-project.org/package=lattice>. However, the format in which the online documentation is written and the breadth of topics covered necessarily makes it somewhat terse and less than ideal as a first introduction. For a more gentle introduction, a book on lattice is available as part of Springer's 'Use R' series; see the "References" section below.

### Note

High-level **lattice** functions like `xyplot` are different from traditional R graphics functions in that they do not perform any plotting themselves. Instead, they return an object, of class "trellis", which has to be then `print`-ed or `plot`-ted to create the actual plot. Due to R's automatic printing rule, it is usually not necessary to explicitly carry out the second step, and **lattice** functions appear to behave like their traditional counterparts. However, the automatic plotting is suppressed when the high-level functions are called inside another function (most often `source`) or in other contexts where automatic printing is suppressed (e.g., `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

The **lattice** package is based on the Grid graphics engine and requires the **grid** add-on package. One consequence of this is that it is not (readily) compatible with traditional R graphics tools. In particular, changing `par()` settings usually has no effect on Lattice plots; **lattice** provides its own interface for querying and modifying an extensive set of graphical and non-graphical settings.

### See Also

The following is a list of high-level functions in the **lattice** package and their default displays. In all cases, the actual display is produced by the so-called "panel" function, which has a suitable default, but can be substituted by an user defined function to create customized displays. In many cases, the default panel function will itself have many optional arguments to customize its output. The default panel functions are named as "panel." followed by the name of the corresponding high-level function; i.e., the default panel function for `xyplot` is `panel.xyplot`, the one for `histogram` is `panel.histogram`, etc. Each default panel function has a separate help page, linked from the help pages of the corresponding high-level function. Although documented separately, arguments to these panel functions can be supplied directly to the high-level functions, which will pass on the arguments appropriately.

#### Univariate:

`barchart`: Bar plots.

`bwplot`: Box-and-whisker plots.

`densityplot`: Kernel density estimates.  
`dotplot`: Cleveland dot plots.  
`histogram`: Histograms.  
`qqmath`: Theoretical quantile plots.  
`stripplot`: One-dimensional scatterplots.

#### **Bivariate:**

`qq`: Quantile plots for comparing two distributions.  
`xypplot`: Scatterplots and time-series plots (and potentially a lot more).

#### **Trivariate:**

`levelplot`: Level plots (similar to `image` plots).  
`contourplot`: Contour plots.  
`cloud`: Three-dimensional scatter plots.  
`wireframe`: Three-dimensional surface plots (similar to `persp` plots).

#### **Hypervariate:**

`splom`: Scatterplot matrices.  
`parallel`: Parallel coordinate plots.

#### **Miscellaneous:**

`rfs`: Residual and fitted value plots (also see `oneway`).  
`tmd`: Tukey Mean-Difference plots.

In addition, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in `panel.functions`. Lattice also provides a collection of convenience functions that correspond to the traditional graphics primitives `lines`, `points`, etc. These are implemented using Grid graphics, but try to be as close to the traditional versions as possible in terms of their argument list. These functions have names like `llines` or `panel.lines` and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Finally, many useful enhancements that extend the Lattice system are available in the **latticeExtra** package.

#### **Examples**

```
## Not run:

## Show brief history of changes to lattice, including
## a summary of new features.

RShowDoc("NEWS", package = "lattice")

## End(Not run)
```

## Description

This help page documents several commonly used high-level Lattice functions. `xyplot` produces bivariate scatterplots or time-series plots, `bwplot` produces box-and-whisker plots, `dotplot` produces Cleveland dot plots, `barchart` produces bar plots, and `stripplot` produces one-dimensional scatterplots. All these functions, along with other high-level Lattice functions, respond to a common set of arguments that control conditioning, layout, aspect ratio, legends, axis annotation, and many other details in a consistent manner. These arguments are described extensively in this help page, and should be used as the reference for other high-level functions as well.

For control and customization of the actual display in each panel, the help page of the respective default panel function will often be more informative. In particular, these help pages describe many arguments commonly used when calling the corresponding high-level function but are specific to them.

## Usage

```
xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

## S3 method for class 'formula'
xyplot(x,
  data,
  allow.multiple = is.null(groups) || outer,
  outer = !is.null(groups),
  auto.key = FALSE,
  aspect = "fill",
  panel = lattice.getOption("panel.xyplot"),
  prepanel = NULL,
  scales = list(),
  strip = TRUE,
  groups = NULL,
  xlab,
  xlim,
  ylab,
  ylim,
  drop.unused.levels = lattice.getOption("drop.unused.levels"),
  ...,
  lattice.options = NULL,
  default.scales,
  default.prepanel = lattice.getOption("prepanel.default.xyplot"),
  subscripts = !is.null(groups),
  subset = TRUE)

## S3 method for class 'formula'
```

```

dotplot(x,
        data,
        panel = lattice.getOption("panel.dotplot"),
        default.prepanel = lattice.getOption("prepanel.default.dotplot"),
        ...)

## S3 method for class 'formula'
barchart(x,
         data,
         panel = lattice.getOption("panel.barchart"),
         default.prepanel = lattice.getOption("prepanel.default.barchart"),
         box.ratio = 2,
         ...)

## S3 method for class 'formula'
stripplot(x,
          data,
          panel = lattice.getOption("panel.stripplot"),
          default.prepanel = lattice.getOption("prepanel.default.stripplot"),
          ...)

## S3 method for class 'formula'
bwplot(x,
       data,
       allow.multiple = is.null(groups) || outer,
       outer = FALSE,
       auto.key = FALSE,
       aspect = "fill",
       panel = lattice.getOption("panel.bwplot"),
       prepanel = NULL,
       scales = list(),
       strip = TRUE,
       groups = NULL,
       xlab,
       xlim,
       ylab,
       ylim,
       box.ratio = 1,
       horizontal = NULL,
       drop.unused.levels = lattice.getOption("drop.unused.levels"),
       ...,
       lattice.options = NULL,
       default.scales,
       default.prepanel = lattice.getOption("prepanel.default.bwplot"),
       subscripts = !is.null(groups),
       subset = TRUE)

```

## Arguments

**x** All high-level function in **lattice** are generic. **x** is the object on which method dispatch is carried out.  
For the "formula" methods, **x** must be a formula describing the primary vari-

ables (used for the per-panel display) and the optional conditioning variables (which define the subsets plotted in different panels) to be used in the plot. Conditioning is described in the “Details” section below.

For the functions documented here, the formula is generally of the form  $y \sim x \mid g1 * g2 * \dots$  (or equivalently,  $y \sim x \mid g1 + g2 + \dots$ ), indicating that plots of  $y$  (on the y-axis) versus  $x$  (on the x-axis) should be produced conditional on the variables  $g1, g2, \dots$ . Here  $x$  and  $y$  are the primary variables, and  $g1, g2, \dots$  are the conditioning variables. The conditioning variables may be omitted to give a formula of the form  $y \sim x$ , in which case the plot will consist of a single panel with the full dataset. The formula can also involve expressions, e.g., `sqrt()`, `log()`, etc. See the `data` argument below for rules regarding evaluation of the terms in the formula.

With the exception of `xyplot`, the functions documented here may also be supplied a formula of the form  $\sim x \mid g1 * g2 * \dots$ . In that case,  $y$  defaults to `names(x)` if  $x$  is named, and a factor with a single level otherwise.

Cases where  $x$  is not a formula is handled by appropriate methods. The `numeric` methods are equivalent to a call with no left hand side and no conditioning variables in the formula. For `barchart` and `dotplot`, non-trivial methods exist for tables and arrays, documented at [barchart.table](#).

The conditioning variables  $g1, g2, \dots$  must be either factors or shingles. Shingles provide a way of using numeric variables for conditioning; see the help page of [shingle](#) for details. Like factors, they have a “levels” attribute, which is used in producing the conditional plots. If necessary, numeric conditioning variables are converted to shingles using the `shingle` function; however, using `equal.count` may be more appropriate in many cases. Character variables are coerced to factors.

**Extended formula interface:** As a useful extension of the interface described above, the primary variable terms (both the LHS  $y$  and RHS  $x$ ) may consist of multiple terms separated by a ‘+’ sign, e.g.,  $y1 + y2 \sim x \mid a * b$ . This formula would be taken to mean that the user wants to plot both  $y1 \sim x \mid a * b$  and  $y2 \sim x \mid a * b$ , but with the  $y1 \sim x$  and  $y2 \sim x$  superposed in each panel. The two groups will be distinguished by different graphical parameters. This is essentially what the `groups` argument (see below) would produce, if  $y1$  and  $y2$  were concatenated to produce a longer vector, with the `groups` argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the `reshape` function. This feature cannot be used in conjunction with the `groups` argument.

To interpret  $y1 + y2$  as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the `outer` argument is set to `TRUE`. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

**Primary variables:** The  $x$  and  $y$  variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of  $x$  and  $y$  should be numeric, and the other a factor or shingle. Which of these will happen is determined by the `horizontal` argument — if `horizontal=TRUE`, then  $y$  will be coerced to be a factor or shingle, otherwise  $x$ . The default value of `horizontal` is

FALSE if `x` is a factor or shingle, TRUE otherwise. (The functionality provided by `horizontal=FALSE` is not S-compatible.)

Note that the `x` argument used to be called `formula` in earlier versions (when the high-level functions were not generic and the `formula` method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but instead be the first (unnamed) argument.

`data` For the `formula` methods, a data frame (or more precisely, anything that is a valid `envir` argument in `eval`, e.g., a list or an environment) containing values for any variables in the formula, as well as `groups` and `subset` if applicable. If not found in `data`, or if `data` is unspecified, the variables are looked for in the environment of the formula. For other methods (where `x` is not a formula), `data` is usually ignored, often with a warning if it is explicitly specified.

`allow.multiple`

Logical flag specifying whether the extended formula interface described above should be in effect. Defaults to TRUE whenever sensible.

`outer`

Logical flag controlling what happens with formulas using the extended interface described above (see the entry for `x` for details). Defaults to FALSE, except when `groups` is explicitly specified or grouping does not make sense for the default panel function.

`box.ratio`

Applicable to `barchart` and `bwplot`. Specifies the ratio of the width of the rectangles to the inter-rectangle space. See also the `box.width` argument in the respective default panel functions.

`horizontal`

Logical flag applicable to `bwplot`, `dotplot`, `barchart`, and `stripplot`. Determines which of `x` and `y` is to be a factor or shingle (`y` if TRUE, `x` otherwise). Defaults to FALSE if `x` is a factor or shingle, TRUE otherwise. This argument is used to process the arguments to these high-level functions, but more importantly, it is passed as an argument to the panel function, which is expected to use it as appropriate.

A potentially useful component of `scales` in this case may be `abbreviate = TRUE`, in which case long labels which would usually overlap will be abbreviated. `scales` could also contain a `minlength` argument in this case, which would be passed to the `abbreviate` function.

**Common arguments:** The following arguments are common to all the functions documented here, as well as most other high-level Trellis functions. These are not documented elsewhere, except to override the usage given here.

`panel`

Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see “Details”), the corresponding `x` and `y` variables (or other variables, as appropriate, in the case of other high-level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the `panel` argument. The argument may be a function object or a character string giving the name of a predefined function. Each high-level function has its own default panel function, named as “`panel.`” followed by the name of the corresponding high-level function (e.g., `panel.xyplot`, `panel.barchart`, etc).

Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named `x` and `y`, which would be provided by the conditioning process. It can also have other arguments. It is useful to know in this context that all arguments passed to a high-level Lattice function (such as `xyplot`) that are not recognized by it are passed through to

the panel function. It is thus generally good practice when defining panel functions to allow a `...` argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics.

Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the `x` and `y` arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric.

Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, as there are several predefined panel functions which can help; for example, `panel.grid`, `panel.loess`, etc. There are also some grid-compatible replacements of commonly used traditional graphics functions useful for this purpose. For example, `lines` can be replaced by `llines` (or equivalently, `panel.lines`). Note that traditional graphics functions like `lines` will not work in a lattice panel function.

One case where a bit more is required of the panel function is when the `groups` argument is not `NULL`. In that case, the panel function should also accept arguments named `groups` and `subscripts` (see below for details). A useful panel function predefined for use in such cases is `panel.superpose`, which can be combined with different `panel.groups` functions to determine what is plotted for each group. See the “Examples” section for an interaction plot constructed in this way. Several other panel functions can also handle the `groups` argument, including the default ones for `xyplot`, `barchart`, `dotplot`, and `stripplot`.

Even when `groups` is not present, the panel function can have `subscripts` as a formal argument. In either case, the `subscripts` argument passed to the panel function are the indices of the `x` and `y` data for that panel in the original data, BEFORE taking into account the effect of the `subset` argument. Note that `groups` remains unaffected by any subsetting operations, so `groups[subscripts]` gives the values of `groups` that correspond to the data in that panel.

This interpretation of `subscripts` does not hold when the extended formula interface is in use (i.e., when `allow.multiple` is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function `latticeParseFormula`), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, `subscripts` needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of `subset`, in which case `subscripts` may have no relationship with corresponding rows in the original data frame.

One can also use functions called `panel.number` and `packet.number`, representing panel order and packet order respectively, inside the panel function (as well as the `strip` function or while interacting with a lattice display using `trellis.focus` etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more condition-

ing variables is altered (using `perm.cond` and `index.cond` respectively), in which case `packet.number` gives the index corresponding to the 'natural' ordering of that combination of levels of the conditioning variables.

`panel.xyplot` has an argument called `type` which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a `groups` variable is used, `panel.xyplot` calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

**aspect** This argument controls the physical aspect ratio of the panels, which is usually the same for all the panels. It can be specified as a ratio (vertical size/horizontal size) or as a character string. In the latter case, legitimate values are `"fill"` (the default) which tries to make the panels as big as possible to fill the available space; `"xy"`, which computes the aspect ratio based on the 45 degree banking rule (see `banking`); and `"iso"` for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel` function are used. Not all default `prepanel` functions produce sensible banking calculations.

**groups** A variable or expression to be evaluated in `data`, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if `groups` is specified, then `groups` along with `subscripts` is passed to the panel function, which is expected to handle these arguments. For high level functions where grouping is appropriate, the default panel functions can handle grouping. It is very common to use a key (legend) when a grouping variable is specified. See entries for `key`, `auto.key` and `simpleKey` for how to draw a key.

**auto.key** A logical, or a list containing components to be used as arguments to `simpleKey`. `auto.key=TRUE` is equivalent to `auto.key=list()`, in which case `simpleKey` is called with a set of default arguments (which may depend on the relevant high-level function). Most valid components to the `key` argument can be specified in this manner, as `simpleKey` will simply add unrecognized arguments to the list it produces.

`auto.key` is typically used to automatically produce a suitable legend in conjunction with a grouping variable. If `auto.key=TRUE`, a suitable legend will be drawn if a `groups` argument is also provided, and not otherwise. In list form, `auto.key` will modify the default legend thus produced. For example, `auto.key=list(columns = 2)` will create a legend split into two columns (`columns` is documented in the entry for `key`).

More precisely, if `auto.key` is not `FALSE`, `groups` is non-null, and there is no `key` or `legend` argument specified in the call, a key is created with `simpleKey` with `levels(groups)` as the first (`text`) argument. (Note: this may not work in all high-level functions, but it does work for the ones where grouping makes sense with the default panel function). If `auto.key` is provided as a list and includes a `text` component, then that is used instead as the text labels in the key, and the key is drawn even if `groups` is not specified. Note that `simpleKey` uses the default settings (see `trellis.par.get`) to determine the graphical parameters in the key, so the resulting legend will

be meaningful only if the same settings are used in the plot as well. The `par.settings` argument, possibly in conjunction with [simpleTheme](#), may be useful to temporarily modify the default settings for this purpose.

One disadvantage to using `key` (or even `simpleKey`) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is re-plotted with different settings, the original parameter settings will be used for the key even though the new settings are used for the actual display. However, with `auto.key`, the key is actually created at plotting time, so the settings will match.

`prepanel`

A function that takes the same arguments as the `panel` function and returns a list, possibly containing components named `xlim`, `ylim`, `dx`, and `dy` (and less frequently, `xat` and `yat`). The return value of a user-supplied `prepanel` function need not contain all these components; in case some are missing, they are replaced by the component-wise defaults.

The `xlim` and `ylim` components are similar to the high level `xlim` and `ylim` arguments (i.e., they are usually a numeric vector of length 2 defining a range, or a character vector representing levels of a factor). If the `xlim` and `ylim` arguments are not explicitly specified (possibly as components in `scales`) in the high-level call, then the actual limits of the panels are guaranteed to include the limits returned by the `prepanel` function. This happens globally if the `relation` component of `scales` is "same", and on a per-panel basis otherwise.

The `dx` and `dy` components are used for banking computations in case `aspect` is specified as "xy". See documentation of [banking](#) for details.

If `xlim` or `ylim` is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first `n` integers, where `n` is the length of `xlim` or `ylim`, as the case may be. The elements of the character vector are used as the default labels for these `n` integers. Thus, to make this information consistent between panels, the `xlim` or `ylim` values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component `xat` or `yat` may be returned by the `prepanel` function, which should be a subset of `1:n`, indicating which of the `n` values (levels) are actually represented in the panel. This is useful when calculating the limits with `relation="free"` or `relation="sliced"` in `scales`.

The `prepanel` function is responsible for providing a meaningful return value when the `x`, `y` (etc.) variables are zero-length vectors. When nothing else is appropriate, values of `NA` should be returned for the `xlim` and `ylim` components.

`strip`

A logical flag or function. If `FALSE`, strips are not drawn. Otherwise, strips are drawn using the `strip` function, which defaults to `strip.default`. See documentation of [strip.default](#) to see the arguments that are available to the `strip` function. This description also applies to the `strip.left` argument (see . . . below), which can be used to draw strips on the left of each panel (useful for wide short panels, e.g., in time-series plots).

`xlab`

Character or expression (or a "grob") giving label(s) for the x-axis. Generally defaults to the expression for `x` in the formula defining the plot. Can be specified as `NULL` to omit the label altogether. Finer control is possible, as described in the

entry for `main`, with the modification that if the `label` component is omitted from the list, it is replaced by the default `xlab`.

`ylab` Character or expression (or `"grob"`) giving label for the y-axis. Generally defaults to the expression for `y` in the formula defining the plot. Finer control is possible, see entries for `main` and `xlab`.

`scales` Generally a list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in `name=value` form, and may also contain two other lists called `x` and `y` of the same form (described below). Components of `x` and `y` affect the respective axes only, while those in `scales` affect both. When parameters are specified in both lists, the values in `x` or `y` are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., `bwplot` has `alternating=FALSE` for the categorical axis only); these can only be overridden by an entry in the corresponding component of `scales`.

As a special exception, `scales` (or its `x` and `y` components) can also be a character string, in which case it is interpreted as the `relation` component.

The possible components are :

`relation` A character string that determines how axis limits are calculated for each panel. Possible values are `"same"` (default), `"free"` and `"sliced"`. For `relation="same"`, the same limits, usually large enough to encompass all the data, are used for all the panels. For `relation="free"`, limits for each panel is determined by just the points in that panel. Behavior for `relation="sliced"` is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the `prepanel` function, which can be overridden by `xlim`, `ylim` or `scales$limits` (except when `relation="sliced"`, in which case explicitly specified limits are ignored with a warning). When `relation` is `"free"`, `xlim` or `ylim` can be a list, in which case it is treated as if its components were the limit values obtained from the `prepanel` calculations for each panel (after being replicated if necessary).

`tick.number` An integer, giving the suggested number of intervals between ticks. This is ignored for a factor, shingle, or character vector, for in these cases there is no natural rule for leaving out some of the labels. But see `xlim`.

`draw` A logical flag, defaulting to `TRUE`, that determines whether to draw the axis (i.e., tick marks and labels) at all.

`alternating` Usually a logical flag specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, `alternating` can also be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers

- 0: do not draw tick labels
- 1: bottom/left
- 2: top/right
- 3: both.

`alternating` applies only when `relation="same"`. The default is `TRUE`, or equivalently, `c(1, 2)`

`limits` Same as `xlim` and `ylim`.

- at** The location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.
- labels** Vector of labels (characters or expressions) to go along with **at**. Can also be a list like **at**.
- cex** A numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top labels separately.
- font, fontface, fontfamily** Specifies the font to be used for axis labels.
- lineheight** Specifies the line height parameter (height of line as a multiple of the size of text); relevant for multi-line labels. (This is currently ignored for **cloud**.)
- tick** Usually a numeric scalar controlling the length of tick marks. Can also be a vector of length 2, to control the length of left/bottom and right/top tick marks separately.
- col** Color of tick marks and labels.
- rot** Angle (in degrees) by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top axes separately.
- abbreviate** A logical flag, indicating whether to abbreviate the labels using the **abbreviate** function. Can be useful for long labels (e.g., in factors), especially on the x-axis.
- minlength** Argument passed to **abbreviate** if **abbreviate=TRUE**.
- log** Controls whether the corresponding variable (**x** or **y**) will be log transformed before being passed to the panel function. Defaults to **FALSE**, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, **TRUE** (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is in reality a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., `scales=list(x = list(log = 2))` is equivalent to  $y \sim \log_2(x)$ . See entry for **equispaced.log** below for details on how to control axis labeling.
- equispaced.log** A logical flag indicating whether tick mark locations should be equispaced when 'log scales' are in use. Defaults to **TRUE**. Tick marks are always labeled in the original (untransformed) scale, but this makes the choice of tick mark locations nontrivial. If **equispaced.log** is **FALSE**, the choice made is similar to how log scales are annotated in traditional graphics. If **TRUE**, tick mark locations are chosen as 'pretty' equispaced values in the transformed scale, and labeled in the form "base^loc", where **base** is the base of the logarithm transformation, and **loc** are the locations in the transformed scale. See also **xscale.components.logpower** in the **latticeExtra** package.
- format** The format to use for POSIXct variables. See **strptime** for description of valid values.
- axis** A character string, "r" (default) or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of **scales** is accomplished by **pscales** in **splom**.

<code>subscripts</code>	A logical flag specifying whether or not a vector named <code>subscripts</code> should be passed to the <code>panel</code> function. Defaults to <code>FALSE</code> , unless <code>groups</code> is specified, or if the <code>panel</code> function accepts an argument named <code>subscripts</code> . This argument is useful if one wants the <code>subscripts</code> to be passed on even if these conditions do not hold; a typical example is when one wishes to augment a Lattice plot after it has been drawn, e.g., using <code>panel.identify</code> .
<code>subset</code>	An expression that evaluates to a logical or integer indexing vector. Like <code>groups</code> , it is evaluated in <code>data</code> . Only the resulting rows of <code>data</code> are used for the plot. If <code>subscripts</code> is <code>TRUE</code> , the <code>subscripts</code> provided to the <code>panel</code> function will be indices referring to the rows of <code>data</code> prior to the subsetting. Whether levels of factors in the <code>data</code> frame that are unused after the subsetting will be dropped depends on the <code>drop.unused.levels</code> argument.
<code>xlim</code>	Normally a numeric vector (or a <code>DateTime</code> object) of length 2 giving left and right limits for the x-axis, or a character vector, expected to denote the levels of <code>x</code> . The latter form is interpreted as a range containing <code>c(1, length(xlim))</code> , with the character vector determining labels at tick positions <code>1:length(xlim)</code> .  <code>xlim</code> could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when <code>scales\$x\$relation</code> is <code>"free"</code> , in which case these are treated as if they were the corresponding limit components returned by <code>prepanel</code> calculations.
<code>ylim</code>	Similar to <code>xlim</code> , applied to the y-axis.
<code>drop.unused.levels</code>	A logical flag indicating whether the unused levels of factors will be dropped, usually relevant when a subsetting operation is performed or an <code>interaction</code> is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components <code>cond</code> and <code>data</code> , both logical, indicating desired behavior for conditioning variables and primary variables respectively. The default is given by <code>lattice.getOption("drop.unused.levels")</code> , which is initially set to <code>TRUE</code> for both components. Note that this argument does not control dropping of levels of the <code>groups</code> argument.
<code>default.scales</code>	A list giving the default values of <code>scales</code> for a particular high-level function. This is rarely of interest to the end-user, but may be helpful when defining other functions that act as a wrapper to one of the high-level Lattice functions.
<code>default.prepanel</code>	A function or character string giving the name of a function that serves as the (component-wise) fallback <code>prepanel</code> function when the <code>prepanel</code> argument is not specified, or does not return all necessary components. The main purpose of this argument is to enable the defaults to be overridden through the use of <code>lattice.options</code> .
<code>lattice.options</code>	A list that could be supplied to <code>lattice.options</code> . These options are applied temporarily for the duration of the call, after which the settings revert back to what they were before. The options are retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the <code>par.settings</code> argument described below for a similar treatment of graphical settings.

...

Further arguments, usually not directly processed by the high-level functions documented here, but instead passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high-level Lattice functions in a similar manner, and those that are meant for the specific panel function being used.

The first group of arguments are processed by a common, unexported function called `trellis.skeleton`. These arguments affect all high-level functions, but are only documented here (except to override the behaviour described here). All other arguments specified in a high-level call, specifically those neither described here nor in the help page of the relevant high-level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high-level function is named as “`panel.`” followed by the name of the high-level function; for example, the default panel function for `bwplot` is `panel.bwplot`. In practical terms, this means that in addition to the help page of the high-level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high-level call.

The effect of the first group of common arguments are as follows:

**as.table:** A logical flag that controls the order in which panels should be displayed: if `FALSE` (the default), panels are drawn left to right, bottom to top (as in a graph); if `TRUE`, left to right, top to bottom (as in a table).

**between:** A list with components `x` and `y` (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). `x` and `y` are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. In other words, it is not possible to use different `between` values for different pages.

**key:** A list that defines a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a “grob” (grid object) eventually plotted by the print method for “trellis” objects. The structure of the legend is constrained in the ways described below.

Although such a list can be and often is created explicitly, it is also possible to generate such a list using the `simpleKey` function; the latter is more convenient but less flexible. The `auto.key` argument can be even more convenient for the most common situation where legends are used, namely, in conjunction with a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by `key`, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of “top”, “bottom”, “left” and “right”. Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0, 0)`, `c(1, 0)`, `c(1, 1)` and `c(0, 1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

`x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the “display area”. Depending on the value of the “`legend.bbox`” option (see `lattice.getOption`), this can be ei-

ther the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The key list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for `rep` below for details on this). The "text" component must have a character or expression vector as its first component, to be used as labels. The length of this vector determines the number of rows.

The graphical components that can be included in key and also in the components named "text", "lines", "points" and "rectangles" (as appropriate) are:

- `cex=1` (text, lines, points)
- `col="black"` (text, rectangles, lines, points)
- `alpha=1` (text, rectangles, lines, points)
- `fill="transparent"` (lines, points)
- `lty=1` (lines)
- `lwd=1` (lines, points)
- `font=1` (text, points)
- `fontface` (text, points)
- `fontfamily` (text, points)
- `pch=8` (lines, points)
- `adj=0` (text)
- `type="l"` (lines)
- `size=5` (rectangles, lines)
- `height=1` (rectangles)
- `lineheight=1` (text)
- `angle=0` (rectangles, but ignored)
- `density=-1` (rectangles, but ignored)

In addition, the component `border` can be included inside the "rect" component to control the border color of the rectangles; when specified at the top level, `border` controls the border of the entire key (see below).

`angle` and `density` are unimplemented. `size` determines the width of columns of rectangles and lines in character widths. `type` is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together. `height` gives heights of rectangles as a fraction of the default.

Other possible components of key are:

`reverse.rows` Logical flag, defaulting to FALSE. If TRUE, all components are reversed *after* being replicated (the details of which may depend on the value of `rep`). This is useful in certain situations, e.g., with a grouped `barchart` with `stack = TRUE` with the categorical variable on the vertical axis, where the bars in the plot will usually

be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom unless `reverse.rows = TRUE`. Note that in this case, unless all columns have the same number of rows, they will no longer be aligned.

`between` Numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides).

`title` String or expression giving a title for the key.

`rep` Logical flag, defaults to `TRUE`. By default, it is assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying `rep=FALSE`, in which case the length of each column will be determined by components of that column alone.

`cex.title` Zoom factor for the title.

`lines.title` The amount of vertical space to be occupied by the title in lines (in multiples of itself). Defaults to 2.

`padding.text` The amount of space (padding) to be used above and below each row containing text, in multiples of the default, which is currently  $0.2 * \text{"lines"}$ . This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.

`background` Background color for the legend. Defaults to the global background color.

`alpha.background` An alpha transparency value between 0 and 1 for the background.

`border` Either a color for the border, or a logical flag. In the latter case, the border color is black if `border` is `TRUE`, and no border is drawn if it is `FALSE` (the default).

`transparent=FALSE` Logical flag, whether legend should have a transparent background.

`just` A character or numeric vector of length one or two giving horizontal and vertical justification for the placement of the legend. See [grid.layout](#) for more precise details.

`columns` The number of column-blocks (drawn side by side) the legend is to be divided into.

`between.columns` Space between column blocks, in addition to `between`.

`divide` Number of point symbols to divide each line when `type` is "b" or "o" in lines.

**legend:** The legend argument can be useful if one wants to place more than one key. It also allows the use of arbitrary "grob"s (grid objects) as legends.

If used, `legend` must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom", or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the `space` component of `key`. If `key` (or `colorkey` for [levelplot](#) and [wireframe](#)) is specified, their `space` component must not conflict with the name of any component of `legend`. Each component of `legend` must have a component called `fun`. This can be a "grob", or a function (or the name of a function) that produces a

"grob" when called. If this function expects any arguments, they must be supplied as a list in another component called `args`. For components named "inside", there can be additional components called `x`, `y` and `corner`, which work in the same way as for `key`.

`page`: A function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

`xlab.top`, `ylab.right`: Labels for the x-axis on top, and y-axis on the right. Similar to `xlab` and `ylab`, but less commonly used.

`main`: Typically a character string or expression describing the main title to be placed on top of each page. Defaults to `NULL`.

`main` (as well as `xlab`, `ylab` and `sub`) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in [plotmath](#). The label can be a vector, in which case the components will be spaced out horizontally (or vertically for `ylab`). This feature can be used to provide column or row labels rather than a single axis label.

When `main` (etc.) is a list, the actual label should be specified as the `label` component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (`xlab` and `ylab` usually have defaults, but `main` and `sub` do not). Further named arguments are passed on to `textGrob`; this can include arguments controlling positioning like `just` and `rot` as well as graphical parameters such as `col` and `font` (see [gpar](#) for a full list).

`main`, `sub`, `xlab`, `ylab`, `xlab.top`, and `ylab.right` can also be arbitrary "grob"s (grid graphical objects).

`sub`: Character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for `main` for finer control options.

`par.strip.text`: A list of parameters to control the appearance of strip text. Notable components are `col`, `cex`, `font`, and `lines`. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "\n"-s) or if the default height seems too small or too large.

Additionally, the `lineheight` component can control the space between multiple lines. The labels can be abbreviated when shown by specifying `abbreviate = TRUE`, in which case the components `minlength` and `dot` (passed along to the [abbreviate](#) function) can be specified to control the details of how this is done.

`layout`: In general, a conditioning plot in Lattice consists of several panels arranged in a rectangular array, possibly spanning multiple pages. `layout` determines this arrangement.

`layout` is a numeric vector of length 2 or 3 giving the number of columns, rows, and pages (optional) in a multipanel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is `c(0, n)`, where `n` is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, tak-

ing into account the aspect ratio of the panels and the device dimensions (via `par("din")`). If NA is specified for the number of rows or columns (but not both), that dimension will be filled out according to the number of panels.

The number of pages is by default set to as many as is required to plot all the panels, and so rarely needs to be specified. However, in certain situations the default calculation may be incorrect, and in that case the number of pages needs to be specified explicitly.

**skip:** A logical vector (default `FALSE`), replicated to be as long as the number of panels (spanning all pages). For elements that are `TRUE`, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This may be useful for arranging plots in an informative manner.

**strip.left:** `strip.left` can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time-series (or similar) plots. See the entry for `strip` for detailed usage.

**xlab.default, ylab.default:** Fallback default for `xlab` and `ylab` when they are not specified. If `NULL`, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Lattice functions.

**xscale.components, yscale.components:** Functions that determine axis annotation for the x and y axes respectively. See documentation for `xscale.components.default`, the default values of these arguments, to learn more.

**axis:** Function responsible for drawing axis annotation. See documentation for `axis.default`, the default value of this argument, to learn more.

**perm.cond:** An integer vector, a permutation of `1:n`, where `n` is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. `perm.cond` can modify this order. If the trellis display is thought of as an `n`-dimensional array, then during printing, its dimensions are permuted using `perm.cond` as the `perm` argument does in `aperm`.

**index.cond:** Whereas `perm.cond` permutes the dimensions of the multi-dimensional array of panels, `index.cond` can be used to subset (or re-order) margins of that array. `index.cond` can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. `index.cond` can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If `index.cond` is a list, it has to be as long as the number of conditioning variables, and the `i`-th component has to be a valid indexing vector for `levels(g_i)`, where `g_i` is the `i`-th conditioning variable in the plot (note that these levels may not contain all levels of the original variable, depending on the effects of the `subset` and `drop.unused.levels` arguments). In particular, this indexing may repeat levels, or drop some altogether. The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to `TRUE`.

Note that the components of `index.cond` are interpreted in the order of the conditioning variables in the original call, and is not affected by

`perm.cond`.

Another possibility is to specify `index.cond` as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a `...` argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) If there is only one conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high-level function calls directly, it is more typical to use `perm.cond` and `index.cond` to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the `update.trellis` method, both can be set to `NULL`, which reverts these back to their defaults.

`par.settings`: A list that could be supplied to `trellis.par.set`. When the resulting object is plotted, these options are applied temporarily for the duration of the plotting, after which the settings revert back to what they were before. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. See also the `lattice.options` argument described above for a similar treatment of non-graphical options.

`plot.args`: A list containing possible arguments to `plot.trellis`, which will be used by the `plot` or `print` methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

## Details

The high-level functions documented here, as well as other high-level Lattice functions, are generic, with the `formula` method usually doing the most substantial work. The structure of the plot that is produced is mostly controlled by the formula (implicitly in the case of the non-formula methods). For each unique combination of the levels of the conditioning variables `g1`, `g2`, ..., a separate "packet" is produced, consisting of the points  $(x, y)$  for the subset of the data defined by that combination. The display can be thought of as a three-dimensional array of panels, consisting of one two-dimensional matrix per page. The dimensions of this array are determined by the `layout` argument. If there are no conditioning variables, the plot produced consists of a single packet. Each packet usually corresponds to one panel, but this is not strictly necessary (see the entry for `index.cond` above).

The coordinate system used by **lattice** by default is like a graph, with the origin at the bottom left, with axes increasing to the right and top. In particular, panels are by default drawn starting from the bottom left corner, going right and then up, unless `as.table = TRUE`, in which case panels are drawn from the top left corner, going right and then down. It is possible to set a global preference for the table-like arrangement by changing the default to `as.table=TRUE`; this can be done by setting `lattice.options(default.args = list(as.table = TRUE))`. Default values can be set in this manner for the following arguments: `as.table`, `aspect`, `between`, `page`, `main`, `sub`, `par.strip.text`, `layout`, `skip` and `strip`. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with `g1` varying fastest, followed by `g2`, and so on. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders

can be modified using the `index.cond` and `perm.cond` arguments, possibly using the `update` (and other related) method(s).

### Value

The high-level functions documented here, as well as other high-level Lattice functions, return an object of class "trellis". The `update` method can be used to subsequently update components of the object, and the `print` method (usually called by default) will plot it on an appropriate plotting device.

### Note

Most of the arguments documented here are also applicable for the other high-level functions in the **lattice** package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high-level plot.

```
require(stats)

## Tonga Trench Earthquakes

Depth <- equal.count(quakes$depth, number=8, overlap=.1)
xyplot(lat ~ long | Depth, data = quakes)
update(trellis.last.object(),
       strip = strip.custom(strip.names = TRUE, strip.levels = TRUE),
       par.strip.text = list(cex = 0.75),
       aspect = "iso")

## Examples with data from 'Visualizing Data' (Cleveland, 1993) obtained
## from http://cm.bell-labs.com/cm/ms/departments/sia/wsc/

EE <- equal.count(ethanol$E, number=9, overlap=1/4)

## Constructing panel functions on the fly; prepanel
```

```

xyplot(NOx ~ C | EE, data = ethanol,
       prepanel = function(x, y) prepanel.loess(x, y, span = 1),
       xlab = "Compression Ratio", ylab = "NOx (micrograms/J)",
       panel = function(x, y) {
         panel.grid(h = -1, v = 2)
         panel.xyplot(x, y)
         panel.loess(x, y, span=1)
       },
       aspect = "xy")

## Extended formula interface

xyplot(Sepal.Length + Sepal.Width ~ Petal.Length + Petal.Width | Species,
       data = iris, scales = "free", layout = c(2, 2),
       auto.key = list(x = .6, y = .7, corner = c(0, 0)))

## user defined panel functions

states <- data.frame(state.x77,
                     state.name = dimnames(state.x77)[[1]],
                     state.region = state.region)
xyplot(Murder ~ Population | state.region, data = states,
       groups = state.name,
       panel = function(x, y, subscripts, groups) {
         ltext(x = x, y = y, labels = groups[subscripts], cex=1,
              fontfamily = "HersheySans")
       })

## Stacked bar chart

barchart(yield ~ variety | site, data = barley,
         groups = year, layout = c(1,6), stack = TRUE,
         auto.key = list(space = "right"),
         ylab = "Barley Yield (bushels/acre)",
         scales = list(x = list(rot = 45)))

bwplot(voice.part ~ height, data=singer, xlab="Height (inches)")

dotplot(variety ~ yield | year * site, data=barley)

## Grouped dot plot showing anomaly at Morris

dotplot(variety ~ yield | site, data = barley, groups = year,
       key = simpleKey(levels(barley$year), space = "right"),
       xlab = "Barley Yield (bushels/acre) ",
       aspect=0.5, layout = c(1,6), ylab=NULL)

stripplot(voice.part ~ jitter(height), data = singer, aspect = 1,
         jitter.data = TRUE, xlab = "Height (inches)")

## Interaction Plot

xyplot(decrease ~ treatment, OrchardSprays, groups = rowpos,
       type = "a",
       auto.key =
       list(space = "right", points = FALSE, lines = TRUE))

```

```
## longer version with no x-ticks

## Not run:

B_01_xyplot.ts	<i>Time series plotting methods</i>
----------------	-------------------------------------

---

## Description

This function handles time series plotting, including cut-and-stack plots. Examples are given of superposing, juxtaposing and styling different time series.

## Usage

```
## S3 method for class 'ts'
xyplot(x, data = NULL,
       screens = if (superpose) 1 else colnames(x),
       ...,
       superpose = FALSE,
       cut = FALSE,
       type = "l",
       col = NULL,
       lty = NULL,
       lwd = NULL,
       pch = NULL,
       cex = NULL,
       fill = NULL,
       auto.key = superpose,
       panel = if (superpose) "panel.superpose"
               else "panel.superpose.plain",
       par.settings = list(),
       layout = NULL, as.table = TRUE,
       xlab = "Time", ylab = NULL,
       default.scales = list(y = list(relation =
                                       if (missing(cut)) "free" else "same")))
```

## Arguments

<code>x</code>	an object of class <code>ts</code> , which may be multi-variate, i.e. have a matrix structure with multiple columns.
----------------	--

<code>data</code>	not used, and must be left as <code>NULL</code> .
<code>...</code>	additional arguments passed to <code>xyplot</code> , which may pass them on to <code>panel.xyplot</code> .
<code>screens</code>	factor (or coerced to factor) whose levels specify which panel each series is to be plotted in. <code>screens = c(1, 2, 1)</code> would plot series 1, 2 and 3 in panels 1, 2 and 1. May also be a named list, see Details below.
<code>superpose</code>	overlays all series in one panel (via <code>screens = 1</code> ) and uses grouped style settings (from <code>trellis.par.get("superpose.line")</code> , etc). Note that this is just a convenience argument: its only action is to change the default values of other arguments.
<code>cut</code>	defines a cut-and-stack plot. <code>cut</code> can be a list of arguments to the function <code>equal.count</code> , i.e. <code>number</code> (number of intervals to divide into) and <code>overlap</code> (the fraction of overlap between cuts, default 0.5). If <code>cut</code> is numeric this is passed as the <code>number</code> argument.  <code>cut = TRUE</code> tries to choose an appropriate number of cuts (up to a maximum of 6), using <code>banking</code> , and assuming a square plot region. This should have the effect of minimising wasted space when <code>aspect = "xy"</code> .
<code>type, col, lty, lwd, pch, cex, fill</code>	graphical arguments, which are processed and eventually passed to <code>panel.xyplot</code> . These arguments can also be vectors or (named) lists, see Details for more information.
<code>auto.key</code>	a logical, or a list describing how to draw a key. See the <code>auto.key</code> entry in <code>xyplot</code> . The default here is to draw lines, not points, and any specified style arguments should show up automatically.
<code>panel</code>	the panel function. It is recommended to leave this alone, but one can pass a <code>panel.groups</code> argument which is handled by <code>panel.superpose</code> for each series.
<code>par.settings</code>	style settings beyond the standard <code>col</code> , <code>lty</code> , <code>lwd</code> , etc; see <code>trellis.par.set</code> and <code>simpleTheme</code> .
<code>layout</code>	numeric vector of length 2 specifying number of columns and rows in the plot. The default is to fill columns with up to 6 rows.
<code>as.table</code>	to draw panels from top to bottom. The order is determined by the order of columns in <code>x</code> .
<code>xlab, ylab</code>	X axis and Y axis labels; see <code>xyplot</code> . Note in particular that <code>ylab</code> may be a character vector, in which case the labels are spaced out equally, to correspond to the panels; but <i>NOTE</i> in this case the vector should be reversed OR the argument <code>as.table</code> set to <code>FALSE</code> .
<code>default.scales</code>	scales specification. The default is set to have "free" Y axis scales unless <code>cut</code> is given. Note, users should pass the <code>scales</code> argument rather than <code>default.scales</code> .

## Details

The handling of several graphical parameters is more flexible for multivariate series. These parameters can be vectors of the same length as the number of series plotted or are recycled if shorter. They can also be (partially) named list, e.g., `list(A = c(1, 2), c(3, 4))` in which `c(3, 4)` is the default value and `c(1, 2)` the value only for series A. The `screens` argument can be specified in a similar way.

Some examples are given below.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Author(s)**

Gabor Grothendieck, Achim Zeileis, Deepayan Sarkar and Felix Andrews <felix@nfrac.org>.

The first two authors developed `xyplot.ts` in their **zoo** package, including the `screens` approach. The third author developed a different `xyplot.ts` for cut-and-stack plots in the **lattice-Extra** package. The final author fused these together.

**References**

Sarkar, Deepayan (2008) *Lattice: Multivariate Data Visualization with R*, Springer. <http://lmdvr.r-forge.r-project.org/> (cut-and-stack plots)

**See Also**

`xyplot`, `panel.xyplot`, `plot.ts`, `ts`, `xyplot.zoo` in the **zoo** package.

**Examples**

```
xyplot(ts(c(1:10,10:1)))

### Figure 14.1 from Sarkar (2008)
xyplot(sunspot.year, aspect = "xy",
       strip = FALSE, strip.left = TRUE,
       cut = list(number = 4, overlap = 0.05))

### A multivariate example; first juxtaposed, then superposed
xyplot(EuStockMarkets, scales = list(y = "same"))
xyplot(EuStockMarkets, superpose = TRUE, aspect = "xy", lwd = 2,
       type = c("l", "g"), ylim = c(0, max(EuStockMarkets)))

### Examples using screens (these two are identical)
xyplot(EuStockMarkets, screens = c(rep("Continental", 3), "UK"))
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"))

### Automatic group styles
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       superpose = TRUE, xlim = extendrange(1996:1998),
       par.settings = standard.theme(color = FALSE))

### Specifying styles for series by name
xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red", FTSE = "blue", "black"), auto.key = TRUE)

xyplot(EuStockMarkets, screens = list(FTSE = "UK", "Continental"),
       col = list(DAX = "red"), lty = list(SMI = 2), lwd = 1:2,
       auto.key = TRUE)
```

```
### Example with simpler data, few data points
set.seed(1)
z <- ts(cbind(a = 1:5, b = 11:15, c = 21:25) + rnorm(5))
xyplot(z, screens = 1)
xyplot(z, screens = list(a = "primary (a)", "other (b & c)"),
       type = list(a = c("p", "h"), b = c("p", "s"), "o"),
       pch = list(a = 2, c = 3), auto.key = list(type = "o"))
```

---

B\_02\_barchart.table

*table methods for barchart and dotplot*

---

## Description

Contingency tables are often displayed using bar charts and dot plots. These methods operate directly on tables, bypassing the need to convert them to data frames for use with the formula interface. Matrices and arrays are also supported, by coercing them to tables.

## Usage

```
## S3 method for class 'table'
barchart(x, data, groups = TRUE,
         origin = 0, stack = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
barchart(x, data, ...)

## S3 method for class 'matrix'
barchart(x, data, ...)

## S3 method for class 'table'
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array'
dotplot(x, data, ...)

## S3 method for class 'matrix'
dotplot(x, data, ...)
```

## Arguments

x	A table, array or matrix object.
data	Should not be specified. If specified, will be ignored with a warning.
groups	A logical flag, indicating whether to use the last dimension as a grouping variable in the display.
origin, stack	Arguments to <a href="#">panel.barchart</a> . The defaults for the table method are different.
horizontal	Logical flag, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.
...	Other arguments, passed to the underlying formula method.

```

breaks,
equal.widths = TRUE,
drop.unused.levels =
  lattice.getOption("drop.unused.levels"),
...,
lattice.options = NULL,
default.scales = list(),
default.prepanel =
  lattice.getOption("prepanel.default.histogram"),
subscripts,
subset)

## S3 method for class 'numeric'
histogram(x, data = NULL, xlab, ...)
## S3 method for class 'factor'
histogram(x, data = NULL, xlab, ...)

## S3 method for class 'formula'
densityplot(x,
  data,
  allow.multiple = is.null(groups) || outer,
  outer = !is.null(groups),
  auto.key = FALSE,
  aspect = "fill",
  panel = lattice.getOption("panel.densityplot"),
  prepanel, scales, strip, groups, weights,
  xlab, xlim, ylab, ylim,
  bw, adjust, kernel, window, width, give.Rkern,
  n = 50, from, to, cut, na.rm,
  drop.unused.levels =
    lattice.getOption("drop.unused.levels"),
  ...,
  lattice.options = NULL,
  default.scales = list(),
  default.prepanel =
    lattice.getOption("prepanel.default.densityplot"),
  subscripts,
  subset)
## S3 method for class 'numeric'
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

```

## Arguments

x	<p>The object on which method dispatch is carried out.</p> <p>For the formula method, x can be a formula of the form <code>~ x   g1 * g2 * ...</code>, indicating that histograms or kernel density estimates of the x variable should be produced conditioned on the levels of the (optional) variables g1, g2, .... x should be numeric (or possibly a factor in the case of histogram), and each of g1, g2, ... should be either factors or shingles.</p>
---	--

As a special case, the right hand side of the formula can contain more than one term separated by '+' signs (e.g.,  $\sim x_1 + x_2 \mid g_1 * g_2$ ). What happens in this case is described in the documentation for [xyplot](#). Note that in either form, all the terms in the formula must have the same length after evaluation.

For the `numeric` and `factor` methods, `x` is the variable whose histogram or Kernel density estimate is drawn. Conditioning is not allowed in these cases.

`data` For the `formula` method, an optional data source (usually a data frame) in which variables are to be evaluated (see [xyplot](#) for details). `data` should not be specified for the other methods, and is ignored with a warning if it is.

`type` A character string indicating the type of histogram that is to be drawn. "percent" and "count" give relative frequency and frequency histograms respectively, and can be misleading when breakpoints are not equally spaced. "density" produces a density histogram.

`type` defaults to "density" when the breakpoints are unequally spaced, and when `breaks` is NULL or a function, and to "percent" otherwise.

`nint` An integer specifying the number of histogram bins, applicable only when `breaks` is unspecified or NULL in the call. Ignored when the variable being plotted is a factor.

`endpoints` A numeric vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when `breaks` is unspecified and the variable being plotted is not a factor. In `do.breaks`, this specifies the interval that is to be divided up.

`breaks` Usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of `type` that makes sense is density.

When `breaks` is unspecified, the value of `lattice.getOption("histogram.breaks")` is first checked. If this value is NULL, then the default is to use

```
breaks = seq_len(1 + nlevels(x)) - 0.5
```

when `x` is a factor, and

```
breaks = do.breaks(endpoints, nint)
```

otherwise. Breakpoints calculated in such a manner are used in all panels. If the retrieved value is not NULL, or if `breaks` is explicitly specified, it affects the display in each panel independently. Valid values are those accepted as the `breaks` argument in [hist](#). In particular, this allows specification of `breaks` as an integer giving the number of bins (similar to `nint`), as a character string denoting a method, or as a function.

When specified explicitly, a special value of `breaks` is NULL, in which case the number of bins is determined by `nint` and then breakpoints are chosen according to the value of `equal.widths`.

`equal.widths` A logical flag, relevant only when `breaks`=NULL. If TRUE, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (typically producing unequally spaced breakpoints).

`n` Integer, giving the number of points at which the kernel density is to be evaluated. Passed on as an argument to [density](#).

<code>panel</code>	A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel functions <code>panel.histogram</code> and <code>panel.densityplot</code> are documented separately, and have arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.
<code>allow.multiple, outer</code>	See <code>xyplot</code> .
<code>auto.key</code>	See <code>xyplot</code> .
<code>aspect</code>	See <code>xyplot</code> .
<code>prepanel</code>	See <code>xyplot</code> .
<code>scales</code>	See <code>xyplot</code> .
<code>strip</code>	See <code>xyplot</code> .
<code>groups</code>	See <code>xyplot</code> . Note that the default panel function for histogram does not support grouped displays, whereas the one for <code>densityplot</code> does.
<code>xlab, ylab</code>	See <code>xyplot</code> .
<code>xlim, ylim</code>	See <code>xyplot</code> .
<code>drop.unused.levels</code>	See <code>xyplot</code> .
<code>lattice.options</code>	See <code>xyplot</code> .
<code>default.scales</code>	See <code>xyplot</code> .
<code>subscripts</code>	See <code>xyplot</code> .
<code>subset</code>	See <code>xyplot</code> .
<code>default.prepanel</code>	Fallback prepanel function. See <code>xyplot</code> .
<code>weights</code>	<p>numeric vector of weights for the density calculations, evaluated in the non-standard manner used for <code>groups</code> and terms in the formula, if any. If this is specified, it is subsetting using <code>subscripts</code> inside the panel function to match it to the corresponding <code>x</code> values.</p> <p>At the time of writing, <code>weights</code> do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).</p>
<code>bw, adjust, width</code>	Arguments controlling bandwidth. Passed on as arguments to <code>density</code> .
<code>kernel, window</code>	The choice of kernel. Passed on as arguments to <code>density</code> .
<code>give.Rkern</code>	Logical flag, passed on as argument to <code>density</code> . This argument is made available only for ease of implementation, and will produce an error if TRUE.
<code>from, to, cut</code>	Controls range over which density is evaluated. Passed on as arguments to <code>density</code> .
<code>na.rm</code>	Logical flag specifying whether NA values should be ignored. Passed on as argument to <code>density</code> , but unlike in <code>density</code> , the default is TRUE.
<code>...</code>	Further arguments. See corresponding entry in <code>xyplot</code> for non-trivial details.

## Details

`histogram` draws Conditional Histograms, and `densityplot` draws Conditional Kernel Density Plots. The default panel function uses the `density` function to compute the density estimate, and all arguments accepted by `density` can be specified in the call to `densityplot` to control the output. See documentation of `density` for details. Note that the default value of the argument `n` of `density` is changed to 50.

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

`do.breaks` is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

## Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

## Note

The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, **lattice** simply passes along the original variable `x` along with the breakpoints. This approach is more flexible; see the example below with an estimated density superimposed over the histogram.

       prepanel = NULL,
       scales, strip, groups,
       xlab, xlim, ylab, ylim,
       drop.unused.levels = lattice.getOption("drop.unused.levels"),
       ...,
       lattice.options = NULL,
       default.scales = list(),
       default.prepanel = lattice.getOption("prepanel.default.qqmath"),
       subscripts,
       subset)
## S3 method for class 'numeric'
qqmath(x, data = NULL, ylab, ...)
```

**Arguments**

- |              |   |
|--------------|---|
| x            | The object on which method dispatch is carried out.<br>For the "formula" method, x should be a formula of the form <code>~ x   g1 * g2 * ...</code> , where x should be a numeric variable. For the "numeric" method, x should be a numeric vector.   |
| data         | For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details). data should not be specified for the other methods, and is ignored with a warning if it is.   |
| distribution | A quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles from a theoretical distribution. Possible values are <a href="#">qnorm</a> , <a href="#">qunif</a> , etc. Distributions with other required arguments need to be provided as user-defined functions (see example with <a href="#">qt</a> ). |

<code>f.value</code>	<p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the <code>quantile</code> function for the sample, and the function specified as the <code>distribution</code> argument for the theoretical distribution.</p> <p><code>f.value</code> defaults to <code>NULL</code>, which has the effect of using <code>ppoints</code> for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for <code>qqnorm</code>, but different from the S-PLUS default of <code>f.value=ppoints</code>.</p> <p>For large <code>x</code>, this argument can be used to restrict the number of points plotted. See also the <code>tails.n</code> argument in <code>panel.qqmath</code>.</p>
<code>panel</code>	<p>A function, called once for each panel, that uses the <code>packet</code> (subset of panel variables) corresponding to the panel to create a display. The default panel function <code>panel.qqmath</code> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.</p>
<code>allow.multiple, outer</code>	See <code>xyplot</code> .
<code>auto.key</code>	See <code>xyplot</code> .
<code>aspect</code>	See <code>xyplot</code> .
<code>prepanel</code>	See <code>xyplot</code> .
<code>scales</code>	See <code>xyplot</code> .
<code>strip</code>	See <code>xyplot</code> .

<code>lattice.options</code>	See <code>xyplot</code> .
<code>default.scales</code>	See <code>xyplot</code> .
<code>subscripts</code>	See <code>xyplot</code> .
<code>subset</code>	See <code>xyplot</code> .
<code>default.prepanel</code>	Fallback <code>prepanel</code> function. See <code>xyplot</code> .
<code>...</code>	Further arguments. See corresponding entry in <code>xyplot</code> for non-trivial details.

## Details

`qqmath` produces Q-Q plots of the given sample against a theoretical distribution. The default behaviour of `qqmath` is different from the corresponding S-PLUS function, but is similar to `qqnorm`. See the entry for `f.value` for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the `panel` (and `prepanel` function) and not `qqmath` itself. In fact, both the

arguments `distribution` and `f.value` are passed unchanged to the panel and prepanel function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for [panel.qqmath](#) for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for [xyplot](#), which should be consulted to learn more detailed usage.

### Value

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

               "[", 2))
qqmath(~ height | vp.comb, data = singer,
       groups = vp.group, auto.key = list(space = "right"),
       aspect = "xy",
       prepanel = prepanel.qqmathline,
       panel = function(x, ...) {
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       })
```

### Description

Quantile-Quantile plots for comparing two Distributions

**Usage**

```
qq(x, data, ...)

## S3 method for class 'formula'
qq(x, data, aspect = "fill",
   panel = lattice.getOption("panel.qq"),
   prepanel, scales, strip,
   groups, xlab, xlim, ylab, ylim, f.value = NULL,
   drop.unused.levels = lattice.getOption("drop.unused.levels"),
   ...,
   lattice.options = NULL,
   qtype = 7,
   default.scales = list(),
   default.prepanel = lattice.getOption("prepanel.default.qq"),
   subscripts,
   subset)
```

**Arguments**

<code>x</code>	<p>The object on which method dispatch is carried out.</p> <p>For the "formula" method, <code>x</code> should be a formula of the form <math>y \sim x \mid g1 * g2 * \dots</math>, where <code>x</code> should be a numeric variable, and <code>y</code> a factor, shingle, character, or numeric variable, with the restriction that there must be exactly two levels of <code>y</code>, which divide the values of <code>x</code> into two groups. Quantiles for these groups will be plotted against each other along the two axes.</p>
<code>data</code>	For the formula method, an optional data source (usually a data frame) in which variables are to be evaluated (see <a href="#">xyplot</a> for details).
<code>f.value</code>	<p>An optional numeric vector of probabilities, quantiles corresponding to which should be plotted. This can also be a function of a single integer (representing sample size) that returns such a numeric vector. A typical value for this argument is the function <code>ppoints</code>, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, through the <code>quantile</code> function.</p> <p><code>f.value</code> defaults to <code>NULL</code>, which is equivalent to</p> <pre>f.value = function(n) ppoints(n, a = 1)</pre> <p>This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for <code>qqplot</code> but different from the default behaviour of <code>qq</code> in S-PLUS.</p> <p>For large <code>x</code>, this argument can be used to restrict the number of quantiles plotted.</p>
<code>panel</code>	A function, called once for each panel, that uses the packet (subset of panel variables) corresponding to the panel to create a display. The default panel function <code>panel.qq</code> is documented separately, and has arguments that can be used to customize its output in various ways. Such arguments can usually be directly supplied to the high-level function.
<code>qtype</code>	The type argument for <a href="#">quantile</a> .
<code>aspect</code>	See <a href="#">xyplot</a> .
<code>prepanel</code>	See <a href="#">xyplot</a> .
<code>scales</code>	See <a href="#">xyplot</a> .

<code>strip</code>	See <a href="#">xyplot</a> .
<code>groups</code>	See <a href="#">xyplot</a> .
<code>xlab, ylab</code>	See <a href="#">xyplot</a> .
<code>xlim, ylim</code>	See <a href="#">xyplot</a> .
<code>drop.unused.levels</code>	See <a href="#">xyplot</a> .
<code>lattice.options</code>	See <a href="#">xyplot</a> .
<code>default.scales</code>	See <a href="#">xyplot</a> .
<code>subscripts</code>	See <a href="#">xyplot</a> .
<code>subset</code>	See <a href="#">xyplot</a> .
<code>default.prepanel</code>	Fallback prepanel function. See <a href="#">xyplot</a> .
<code>...</code>	Further arguments. See corresponding entry in <a href="#">xyplot</a> for non-trivial details.

            row.values = seq_len(nrow(x)),
            column.values = seq_len(ncol(x)))

## S3 method for class 'array'
levelplot(x, data = NULL, ...)

## S3 method for class 'array'
contourplot(x, data = NULL, ...)

```

## Arguments

**x** for the formula method, a formula of the form  $z \sim x * y$  |  $g1 * g2 * \dots$ , where  $z$  is a numeric response, and  $x$ ,  $y$  are numeric values evaluated on a rectangular grid.  $g1$ ,  $g2$ ,  $\dots$  are optional conditional variables, and must be either factors or shingles if present.

Calculations are based on the assumption that all  $x$  and  $y$  values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the  $x$  and  $y$  values need not be equally spaced.

Both `levelplot` and `wireframe` have methods for `matrix`, `array`, and `table` objects, in which case  $x$  provides the  $z$  vector described above, while its rows and columns are interpreted as the  $x$  and  $y$  vectors respectively. This is similar to the form used in `filled.contour` and `image`. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the `dimnames` may be duplicated; this is handled by calling `make.unique` to make the names unique (although the original labels are used for the  $x$ - and  $y$ -axes).

<code>data</code>	For the formula methods, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usually ignored with a warning in other cases.
<code>row.values, column.values</code>	Optional vectors of values that define the grid when <code>x</code> is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.
<code>panel</code>	panel function used to create the display, as described in <a href="#">xyplot</a>
<code>aspect</code>	For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is <code>aspect="fill"</code> , as described in <a href="#">xyplot</a> .
<code>at</code>	A numeric vector giving breakpoints along the range of <code>z</code> . Contours (if any) will be drawn at these heights, and the regions in between would be colored using <code>col.regions</code> . In the latter case, values outside the range of <code>at</code> will not be drawn at all. This serves as a way to limit the range of the data shown, similar to what a <code>zlim</code> argument might have been used for. However, this also means that when supplying <code>at</code> explicitly, one has to be careful to include values outside the range of <code>z</code> to ensure that all the data are shown. <code>at</code> can have length one only if <code>region=FALSE</code> .
<code>col.regions</code>	color vector to be used if regions is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than colors in <code>col.regions</code> , the colors are recycled. The actual color assignment is performed by <a href="#">level.colors</a> , which is documented separately.
<code>alpha.regions</code>	numeric, specifying alpha transparency (works only on some devices)
<code>colorkey</code>	logical specifying whether a color key is to be drawn alongside the plot, or a list describing the color key. The list may contain the following components: <code>space</code> : location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right". <code>x, y</code> : location, currently unused <code>col</code> : A color ramp specification, as in the <code>col.regions</code> argument in <a href="#">level.colors</a> <code>at</code> : numeric vector specifying where the colors change. must be of length 1 more than the <code>col</code> vector. <code>labels</code> : a character vector for labelling the <code>at</code> values, or more commonly, a list describing characteristics of the labels. This list may include components <code>labels</code> , <code>at</code> , <code>cex</code> , <code>col</code> , <code>rot</code> , <code>font</code> , <code>fontface</code> and <code>fontfamily</code> . <code>tick.number</code> : The approximate number of ticks desired. <code>tck</code> : A (scalar) multiplier for tick lengths. <code>corner</code> : Interacts with <code>x, y</code> ; currently unimplemented <code>width</code> : The width of the key <code>height</code> : The length of key as a fraction of the appropriate side of plot. <code>raster</code> : A logical flag indicating whether the colorkey should be rendered as a raster image using <a href="#">grid.raster</a> . See also <a href="#">panel.levelplot.raster</a> .

	<code>interpolate</code> : Logical flag, passed to <code>rasterGrob</code> when <code>raster=TRUE</code> .
	<code>axis.line</code> : A list giving graphical parameters for the color key boundary and tick marks. Defaults to <code>trellis.par.get("axis.line")</code> .
	<code>axis.text</code> : A list giving graphical parameters for the tick mark labels on the color key. Defaults to <code>trellis.par.get("axis.text")</code> .
<code>contour</code>	A logical flag, indicating whether to draw contour lines.
<code>cuts</code>	The number of levels the range of <code>z</code> would be divided into.
<code>labels</code>	Typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for <code>panel.levelplot</code> , to which this argument is passed on unchanged. That help page also documents the <code>label.style</code> argument, which affects how the labels are rendered.
<code>pretty</code>	A logical flag, indicating whether to use pretty cut locations and labels.
<code>region</code>	A logical flag, indicating whether regions between contour lines should be filled as in a level plot.
<code>allow.multiple</code> , <code>outer</code> , <code>prepanel</code> , <code>scales</code> , <code>strip</code> , <code>groups</code> , <code>xlab</code> , <code>xlim</code> , <code>ylab</code> , <code>ylim</code> ,	These arguments are described in the help page for <code>xyplot</code> .
<code>default.prepanel</code>	Fallback prepanel function. See <code>xyplot</code> .
<code>...</code>	Further arguments may be supplied. Some are processed by <code>levelplot</code> or <code>contourplot</code> , and those that are unrecognized are passed on to the panel function.
<code>useRaster</code>	<p>A logical flag indicating whether raster representations should be used, both for the false color image and the color key (if present). Effectively, setting this to <code>TRUE</code> changes the default panel function from <code>panel.levelplot</code> to <code>panel.levelplot.raster</code>, and sets the default value of <code>colorkey\$raster</code> to <code>TRUE</code>.</p> <p>Note that <code>panel.levelplot.raster</code> provides only a subset of the features of <code>panel.levelplot</code>, but setting <code>useRaster=TRUE</code> will not check whether any of the additional features have been requested.</p> <p>Not all devices support raster images. For devices that appear to lack support, <code>useRaster=TRUE</code> will be ignored with a warning.</p>

## Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function `panel.levelplot` (these are formally arguments to the panel function, but can be specified in the high level calls directly).

## Value

An object of class `"trellis"`. The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

cloud(x, data = NULL, groups = FALSE,
      zlab = deparse(substitute(x)),
      type = "h", ...)

## S3 method for class 'matrix'
wireframe(x, data = NULL,
          zlab = deparse(substitute(x)), aspect, ...,
          xlim, ylim, row.values, column.values)
```

## Arguments

- x** The object on which method dispatch is carried out.
- For the "formula" methods, a formula of the form  $z \sim x * y \mid g_1 * g_2 * \dots$ , where  $z$  is a numeric response, and  $x, y$  are numeric values.  $g_1, g_2, \dots$ , if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of `wireframe`, calculations are based on the assumption that the  $x$  and  $y$  values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.
- For `wireframe`,  $x, y$  and  $z$  may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.
- Missing values are allowed, either as NA values in the  $z$  vector, or missing rows in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in  $z$  are.
- Both `wireframe` and `cloud` have methods for `matrix` objects, in which case  $x$  provides the  $z$  vector described above, while its rows and columns are interpreted as the  $x$  and  $y$  vectors respectively. This is similar to the form used in `persp`.
- data** for the "formula" methods, an optional data frame in which variables in the formula (as well as `groups` and `subset`, if any) are to be evaluated. `data` should not be specified except when using the "formula" method.
- row.values, column.values** Optional vectors of values that define the grid when  $x$  is a matrix. `row.values` and `column.values` must have the same lengths as `nrow(x)` and `ncol(x)` respectively. By default, row and column numbers.
- allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim** These arguments are documented in the help page for `xyplot`. For the `cloud.table` method, `groups` must be a logical indicating whether the last dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.
- type** type of display in `cloud` (see `panel.3dscatter` for details). Defaults to "h" for the `matrix` method.
- aspect, panel.aspect** Unlike other high level functions, `aspect` is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the

enclosing cube. The usual role of the `aspect` argument in determining the aspect ratio of the panel (see `xyplot` for details) is played by `panel.aspect`, except that it can only be a numeric value.

For the `matrix` methods, the default `y/x` aspect is `ncol(x) / nrow(x)` and the `z/x` aspect is the smaller of the `y/x` aspect and 1.

<code>panel</code>	panel function used to create the display. See <code>panel.cloud</code> for (non-trivial) details.
<code>default.prepanel</code>	Fallback <code>prepanel</code> function. See <code>xyplot</code> .
<code>scales</code>	<p>a list describing the scales. As with other high level functions (see <code>xyplot</code> for details), this list can contain parameters in <code>name=value</code> form. It can also contain components with the special names <code>x</code>, <code>y</code> and <code>z</code>, which can be similar lists with axis-specific values overriding the ones specified in <code>scales</code>.</p> <p>The most common use for this argument is to set <code>arrows=FALSE</code>, which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by <code>draw=FALSE</code>. Another special component is <code>distance</code>, which specifies the relative distance of the axis label from the bounding box. If specified as a component of <code>scales</code> (as opposed to one of <code>scales\$z</code> etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the <code>x</code>, <code>y</code> and <code>z</code> labels respectively.</p> <p>Other components that work in the <code>scales</code> argument of <code>xyplot</code> etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.)</p> <p>Note, however, that for these functions <code>scales</code> cannot contain information that is specific to particular panels. If you really need that, consider using the <code>scales.3d</code> argument of <code>panel.cloud</code>.</p>
<code>axis.default</code>	Unlike 2-D display functions, <code>cloud</code> does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in <code>wireframe</code> , which uses the same code. <code>axis.default</code> is intended to provide a different default for <code>cloud</code> . However, this feature has not yet been implemented.
<code>zlab</code>	Specifies a label describing the <code>z</code> variable in ways similar to <code>xlab</code> and <code>ylab</code> (i.e. “grob”, character string, expression or list) in other high level functions. Additionally, if <code>zlab</code> (and <code>xlab</code> and <code>ylab</code> ) is a list, it can contain a component called <code>rot</code> , controlling the rotation for the label
<code>zlim</code>	limits for the <code>z</code> -axis. Similar to <code>xlim</code> and <code>ylim</code> in other high level functions
<code>drape</code>	logical, whether the wireframe is to be draped in color. If <code>TRUE</code> , the height of a facet is used to determine its color in a manner similar to the coloring scheme used in <code>levelplot</code> . Otherwise, the background color is used to color the facets. This argument is ignored if <code>shade = TRUE</code> (see <code>panel.3dwire</code> ).
<code>at</code> , <code>col.regions</code> , <code>alpha.regions</code>	these arguments are analogous to those in <code>levelplot</code> . if <code>drape=TRUE</code> , <code>at</code> gives the vector of cutpoints where the colors change, and <code>col.regions</code> the vector of colors to be used in that case. <code>alpha.regions</code> determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for <code>col.regions</code> and <code>alpha.regions</code> is derived from the Trellis setting “regions”
<code>cuts</code>	if <code>at</code> is unspecified, the approximate number of cutpoints if <code>drape=TRUE</code>

<code>pretty</code>	whether automatic choice of cutpoints should be prettfied
<code>colorkey</code>	logical indicating whether a color key should be drawn alongside, or a list describing such a key. See <a href="#">levelplot</a> for details.
<code>...</code>	Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments <code>distance</code> , <code>perspective</code> , <code>screen</code> and <code>R.mat</code> are very important in determining the 3-D display. The argument <code>shade</code> can be useful for <code>wireframe</code> calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for <a href="#">panel.cloud</a> .  Additionally, an argument called <code>zoom</code> may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default <code>prepanel</code> function.

## Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the  $[-0.5, 0.5]$  cube (even smaller for non-default values of `aspect`). The viewing direction is given by a sequence of rotations specified by the `screen` argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of  $1/\text{distance}$  from the origin. If `perspective=FALSE`, `distance` is set to 0 (i.e., the viewing point is at an infinite distance).

`cloud` draws a 3-D Scatter Plot, while `wireframe` draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by `wireframe` using the `groups` argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying `groups` with `cloud` results in a `panel.superpose`-like effect (via [panel.3dscatter](#)).

`wireframe` can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for [panel.3dwire](#). Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form  $f(u,v) = (x(u,v), y(u,v), z(u,v))$ , where values of  $(u,v)$  lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved by calling `wireframe` with a formula `x` of the form `z~x*y`, where `x`, `y` and `z` are all matrices of the same dimension, representing the values of  $x(u,v)$ ,  $y(u,v)$  and  $z(u,v)$  evaluated on a discrete rectangular grid (the actual values of  $(u,v)$  are irrelevant).

When this feature is used, the heights used to calculate drape colors or shading colors are no longer the  $z$  values, but the distances of  $(x, y, z)$  from the origin.

Note that this feature does not work with `groups`, `subscripts`, `subset`, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, [panel.cloud](#) tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in [panel.cloud](#).

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for [xyplot](#), which should be consulted to learn more detailed usage.

**Value**

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

**Note**

There is a known problem with grouped `wireframe` displays when the (x, y) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

```

## Arguments

<code>x</code>	<p>The object on which method dispatch is carried out.</p> <p>For the "formula" method, a formula describing the structure of the plot, which should be of the form <code>~ x   g1 * g2 * ...</code>, where <code>x</code> is a data frame or matrix. Each of <code>g1, g2, ...</code> must be either factors or shingles. The conditioning variables <code>g1, g2, ...</code> may be omitted.</p> <p>For the <code>data.frame</code> methods, a data frame.</p>
<code>data</code>	For the <code>formula</code> methods, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated.
<code>aspect</code>	aspect ratio of each panel (and subpanel), square by default for <code>splom</code> .
<code>between</code>	to avoid confusion between panels and subpanels, the default is to show the panels of a <code>splom</code> plot with space between them.
<code>panel</code>	For <code>parallelplot</code> , this has the usual interpretation, i.e., a function that creates the display within each panel.

For `splo`m, the terminology is slightly complicated. The role played by the `panel` function in most other high-level functions is played here by the `superpanel` function, which is responsible for the display for each conditional data subset. `panel` is simply an argument to the default `superpanel` function `panel.pairs`, and is passed on to it unchanged. It is used there to create each pairwise display. See [panel.pairs](#) for more useful options.

<code>superpanel</code>	function that sets up the <code>splo</code> m display, by default as a scatterplot matrix.
<code>pscales</code>	a numeric value or a list, meant to be a less functional substitute for the <code>scales</code> argument in <code>xyplot</code> etc. This argument is passed to the <code>superpanel</code> function, and is handled by the default <code>superpanel</code> function <code>panel.pairs</code> . The help page for the latter documents this argument in more detail.
<code>varnames</code>	A character or expression vector or giving names to be used for the variables in <code>x</code> . By default, the column names of <code>x</code> .
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
<code>auto.key</code> , <code>prepanel</code> , <code>scales</code> , <code>strip</code> , <code>groups</code> , <code>xlab</code> , <code>xlim</code> , <code>ylab</code> , <code>ylim</code> , <code>drop.unused.l</code>	See <a href="#">xyplot</a>
<code>default.prepanel</code>	Fallback <code>prepanel</code> function. See <a href="#">xyplot</a> .
<code>...</code>	Further arguments. See corresponding entry in <a href="#">xyplot</a> for non-trivial details.

## Details

`splo`m produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both `x`- and `y`-limits from `0.5` to `ncol(z) + 0.5`. The only built-in option currently available is [panel.pairs](#), which calls a further `panel` function for each pair `(i, j)` of variables in `z` inside a rectangle of unit width and height centered at `c(i, j)` (see [panel.pairs](#) for details).

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splo`m. These include control of axis limits, tick locations and `prepanel` calculations. If you are trying to fine-tune your `splo`m plot, definitely look at the [panel.pairs](#) help page. The `scales` argument is usually not very useful in `splo`m, and trying to change it may have undesired effects.

[parallelplot](#) draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

## Value

An object of class `"trellis"`. The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

```

B\_09\_tmd

*Tukey Mean-Difference Plot***Description**

tmd Creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The `prepanel` and `panel` functions are used as appropriate. The formula method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

**Usage**

```
tmd(object, ...)
```

```
## S3 method for class 'trellis'
tmd(object,
     xlab = "mean",
     ylab = "difference",
     panel,
     prepanel,
     ...)
```

```
prepanel.tmd.qqmath(x,
                    f.value = NULL,
                    distribution = qnorm,
                    qtype = 7,
```

```

        groups = NULL,
        subscripts, ...)
panel.tmd.qqmath(x,
        f.value = NULL,
        distribution = qnorm,
        qtype = 7,
        groups = NULL,
        subscripts, ...,
        identifier = "tmd")
panel.tmd.default(x, y, groups = NULL, ...,
        identifier = "tmd")
prepanel.tmd.default(x, y, ...)

```

### Arguments

<code>object</code>	An object of class "trellis" returned by <code>xyplot</code> , <code>qq</code> or <code>qqmath</code> .
<code>xlab</code>	x label
<code>ylab</code>	y label
<code>panel</code>	panel function to be used. See details below.
<code>prepanel</code>	prepanel function. See details below.
<code>f.value</code> , <code>distribution</code> , <code>qtype</code>	see <a href="#">panel.qqmath</a> .
<code>groups</code> , <code>subscripts</code>	see <a href="#">xyplot</a> .
<code>x</code> , <code>y</code>	data as passed to panel functions in original call.
<code>...</code>	other arguments
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

### Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by  $x = (x+y)/2$  and  $y = y - x$ , which are then plotted. The default panel function(s) add a reference line at  $y=0$  as well.

`tmd` acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. `tmd` uses these panel arguments to set up its own scales (using its `prepanel` argument) and display (using `panel`). It is thus important to provide suitable `prepanel` and `panel` functions to `tmd` depending on the original call.

Such functions currently exist for `xyplot`, `qq` (the ones with `default` in their name) and `qqmath`, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the `prepanel` and `panel` arguments default to suitable choices.

`tmd` uses the `update` method for "trellis" objects, which processes all extra arguments supplied to `tmd`.

**Value**

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

*Residual and Fit Spread Plots*

---

**Description**

Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

**Usage**

```
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
     distribution = qunif,
     panel, prepanel, strip, ...)
```

**Arguments**

model	a fitted model object with methods <code>fitted.values</code> and <code>residuals</code> . Can be the value returned by <code>oneway</code>
layout	default layout is <code>c(2,1)</code>
xlab	defaults to <code>"f.value"</code>
distribution	the distribution function to be used for <code>qqmath</code>
ylab, panel, prepanel, strip	See <a href="#">xyplot</a>
...	other arguments, passed on to <a href="#">qqmath</a> .

**Value**

An object of class "trellis". The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

B\_11\_oneway

*Fit One-way Model*

---

**Description**

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`

**Usage**

```
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

**Arguments**

<code>formula</code>	formula of the form $y \sim x$ where $y$ is the numeric response and $x$ is the grouping factor
<code>data</code>	data frame in which the model is to be evaluated
<code>location</code>	function or numeric giving the location statistic to be used for centering the observations, e.g. <code>median</code> , 0 (to avoid centering).
<code>spread</code>	function or numeric giving the spread statistic to be used for scaling the observations, e.g. <code>sd</code> , 1 (to avoid scaling).

**Value**

A list with components

<code>location</code>	vector of locations for each group.
<code>spread</code>	vector of spreads for each group.
<code>fitted.values</code>	vector of locations for each observation.
<code>residuals</code>	residuals ( $y - \text{fitted.values}$ ).
<code>scaled.residuals</code>	residuals scaled by spread for their group

**Usage**

```
trellis.device(device = getOption("device"),
               color = !(dev.name == "postscript"),
               theme = lattice.getOption("default.theme"),
               new = TRUE,
               retain = FALSE,
               ...)

standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()
```

**Arguments**

- |        |  |
|--------|--|
| device | function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see <a href="#">Devices</a> ), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.  |
| color  | logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using <code>theme</code> or subsequent calls to <code>trellis.par.set</code> (and by arguments supplied directly in high level calls for some settings).  |
| theme  | list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying <code>lattice.options(default.theme = "col.whitebg")</code> . For back-compatibility, this is initially (when lattice is loaded) set to <code>getOption(lattice.theme)</code> .<br>If <code>theme</code> is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use <code>.Device</code> inside the function to ascertain what device has been opened. |
| new    | logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.  |
| retain | logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).  |

name	name of the device for which the setting is required, as returned by <code>.Device</code>
...	additional parameters to be passed to the <code>device</code> function, most commonly <code>file</code> for non-screen devices, as well as <code>height</code> , <code>width</code> , etc. See the help file for individual devices for admissible arguments.

## Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a “trellis” object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default `theme` argument, e.g. by putting `lattice.options(default.theme = "standard.theme")` in a startup script (see the entry for `theme` above for details).

## Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the `theme` argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`.

`col.whitebg` returns a similar (but smaller) list that is suitable as the `theme` argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

## Note

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

[trellis.par.get](#) and [trellis.par.set](#) can be used to query and modify the settings *after* a device has been initialized. The `par.settings` argument to high level functions, described in [xyplot](#), can be used to attach transient settings to a "trellis" object.

---

C\_02\_trellis.par.get

*Graphical Parameters for Trellis Displays*

---

**Description**

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

**Usage**

```
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)
```

**Arguments**

name	A character string giving the name of a component. If unspecified in <code>trellis.par.get()</code> , the return value is a named list containing all the current settings (this can be used to get the valid values for name).
value	a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in <code>value</code> will remain unchanged.
theme	a list describing how to change the settings, similar to what is returned by <code>trellis.par.get()</code> . This is purely for convenience, allowing multiple calls to <code>trellis.par.set</code> to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above.  As in <a href="#">trellis.device</a> , <code>theme</code> can also be a function that produces such a list when called. The function name can be supplied as a quoted string.
...	Multiple settings can be specified in <code>name = value</code> form. Equivalent to calling with <code>theme = list(...)</code>
warn	A logical flag, indicating whether a warning should be issued when <code>trellis.par.get</code> is called when no graphics device is open.
strict	Usually a logical flag, indicating whether the <code>value</code> should be interpreted strictly. Usually, assignment of value to the corresponding named component is fuzzy in the sense that sub-components that are absent from <code>value</code> but not currently <code>NULL</code> are retained. By specifying <code>strict = TRUE</code> , such values will be removed.  An even stricter interpretation is allowed by specifying <code>strict</code> as a numeric value larger than 1. In that case, top-level components not specified in the call will also be removed. This is primarily for internal use.

- x optional list of components that change the settings (any valid value of theme). These are used to modify the current settings (obtained by `trellis.par.get`) before they are displayed.

## Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (`color postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a `postscript` device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
```

```
add.line$col <- "red"
```

```
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
```

and

```
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I'm not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

## Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Most of the settings are graphical parameters that control various elements of a lattice plot. For details, see the examples below. The more unusual settings are described here.

```

        panel.xyplot(x, y, pch = 16 * z, ...)
    },
    xlab = "Graphical parameters",
    ylab = "Setting names")

```

---

C\_03\_simpleTheme      *Function to generate a simple theme*

---

## Description

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

## Usage

```

simpleTheme(col, alpha,
            cex, pch, lty, lwd, font, fill, border,
            col.points, col.line,
            alpha.points, alpha.line)

```

## Arguments

`col`, `col.points`, `col.line`

A color specification. `col` is used for components `"plot.symbol"`, `"plot.line"`, `"plot.polygon"`, `"superpose.symbol"`, `"superpose.line"`, and `"superpose.polygon"`. `col.points` overrides `col`, but is used only for `"plot.symbol"` and `"superpose.symbol"`. Similarly, `col.line` overrides `col` for `"plot.line"` and `"superpose.line"`. The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without `"superpose"` in their name).

`alpha`, `alpha.points`, `alpha.line`

A numeric alpha transparency specification. The same rules as `col`, etc., apply.

`cex`, `pch`, `font`

Parameters for points. Applicable for components `plot.symbol` (for which only the first component is used) and `superpose.symbol` (for which the arguments can be vectors).

`lty`, `lwd`

Parameters for lines. Applicable for components `plot.line` (for which only the first component is used) and `superpose.line` (for which the arguments can be vectors).

`fill`

fill color, applicable for components `plot.symbol`, `plot.polygon`, `superpose.symbol`, and `superpose.polygon`.

`border`

border color, applicable for components `plot.polygon` and `superpose.polygon`.

## Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see `trellis.device` for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in simple `name=value` form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

## Value

A list that would work as the `theme` argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>, based on a suggestion from John Maindonald.

dotplot(variety ~ yield | site, data = barley, groups = year,
        auto.key = list(space = "right"),
        par.settings = simpleTheme(pch = 16),
        xlab = "Barley Yield (bushels/acre) ",
        aspect=0.5, layout = c(1,6))
```

---

C\_04\_lattice.options

*Low-level Options Controlling Behaviour of Lattice*

---

## Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level may be useful in certain cases.

## Usage

```
lattice.options(...)
lattice.getOption(name)
```

## Arguments

<code>name</code>	character giving the name of a setting
<code>...</code>	new options can be defined, or existing ones modified, using one or more arguments of the form <code>name = value</code> or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

## Details

These functions are modeled on `options` and `getOption`, and behave similarly for the most part. Some of the available components are documented here, but not all. The purpose of the ones not documented are either fairly obvious, or not of interest to the end-user.

`panel.error` A function, or `NULL`. If the former, every call to the `panel` function will be wrapped inside `tryCatch` with the specified function as an error handler. The default is to use the `panel.error` function. This prevents the plot from failing due to errors in a single panel, and leaving the grid operations in an unmanageable state. If set to `NULL`, errors in panel functions will not be caught using `tryCatch`.

`save.object` Logical flag indicating whether a "trellis" object should be saved when plotted for subsequent retrieval and further manipulation. Defaults to `TRUE`.

`layout.widths`, `layout.heights` Controls details of the default space allocation in the grid layout created in the course of plotting a "trellis" object. Each named component is a list of arguments to the `grid` function `unit` (x, units, and optionally data).

Usually not of interest to the end-user, who should instead use the similarly named component in the graphical settings, modifiable using `trellis.par.set`.

`drop.unused.levels` A list of two components named `cond` and `data`, both logical flags. The flags indicate whether the unused levels of factors (conditioning variables and primary variables respectively) will be dropped, which is usually relevant when a subsetting operation is performed or an 'interaction' is created. See `xyplot` for more details. Note that this does not control dropping of levels of the 'groups' argument.

`legend.bbox` A character string, either "full" or "panel". This determines the interpretation of x and y when `space="inside"` in `key` (determining the legend; see `xyplot`): either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

`default.args` A list giving default values for various standard arguments: `as.table`, `aspect`, `between`, `skip`, `strip`, `xscale.components`, `yscale.components`, and `axis`.

`highlight.gpar` A list giving arguments to `gpar` used to highlight a viewport chosen using `trellis.focus`.

`banking` The `banking` function. See `banking`.

`axis.padding` List with components named "numeric" and "factor", both scalar numbers. Panel limits are extended by this amount, to provide padding for numeric and factor scales respectively. The value for numeric is multiplicative, whereas factor is additive.

`skip.boundary.labels` Numeric scalar between 0 and 1. Tick marks that are too close to the limits are not drawn unless explicitly requested. The limits are contracted by this proportion, and anything outside is skipped.

`interaction.sep` The separator for creating interactions with the extended formula interface (see `xyplot`).

`axis.units` List determining default units for axis components. Should not be of interest to the end-user.

In addition, there is an option for the default `prepanel` and `panel` function for each high-level function; e.g., `panel.xyplot` and `prepanel.default.xyplot` for `xyplot`. The options for the others have similarly patterned names.

### Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

C\_05\_print.trellis *Plot and Summarize Trellis Objects*

---

### Description

The `print` and `plot` methods produce a graph from a "trellis" object. The `print` method is necessary for automatic plotting. `plot` method is essentially an alias, provided for convenience. The `summary` method gives a textual summary of the object. `dim` and `dimnames` describe the cross-tabulation induced by conditioning. `panel.error` is the default handler used when an error occurs while executing the panel function.

### Usage

```
## S3 method for class 'trellis'
plot(x, position, split,
      more = FALSE, newpage = TRUE,
      packet.panel = packet.panel.default,
      draw.in = NULL,
      panel.height = lattice.getOption("layout.heights")$panel,
      panel.width = lattice.getOption("layout.widths")$panel,
      save.object = lattice.getOption("save.object"),
      panel.error = lattice.getOption("panel.error"),
      prefix,
      ...)
## S3 method for class 'trellis'
```

```

print(x, ...)

## S3 method for class 'trellis'
summary(object, ...)

## S3 method for class 'trellis'
dim(x)
## S3 method for class 'trellis'
dimnames(x)

panel.error(e)

```

### Arguments

<code>x</code> , <code>object</code>	an object of class "trellis"
<code>position</code>	a vector of 4 numbers, typically <code>c(xmin, ymin, xmax, ymax)</code> that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of <code>x</code> is to be positioned. The coordinate system for this rectangle is [0-1] in both the <code>x</code> and <code>y</code> directions.
<code>split</code>	a vector of 4 integers, <code>c(x,y,nx,ny)</code> , that says to position the current plot at the <code>x,y</code> position in a regular array of <code>nx</code> by <code>ny</code> plots. (Note: this has origin at top left)
<code>more</code>	A logical specifying whether more plots will follow on this page.
<code>newpage</code>	A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).
<code>packet.panel</code>	a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function <code>packet.panel.default</code> , whose help page details the arguments supplied to whichever function is specified as the <code>packet.panel</code> argument.
<code>draw.in</code>	An optional (grid) viewport (used as the <code>name</code> argument in <code>downViewport</code> ) in which the plot is to be drawn. If specified, the <code>newpage</code> argument is ignored. This feature is not well-tested.
<code>panel.width</code> , <code>panel.height</code>	lists with 2 components, that should be valid <code>x</code> and <code>units</code> arguments to <code>unit()</code> (the <code>data</code> argument cannot be specified currently, but can be considered for addition if needed). The resulting <code>unit</code> object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.  Note that this option should not be used in conjunction with non-default values of the <code>aspect</code> argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).

<code>save.object</code>	logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel's data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the <code>update</code> method on the current plot, even if it was not assigned to a variable explicitly. For more details, see <a href="#">trellis.focus</a> .
<code>panel.error</code>	a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using <a href="#">tryCatch</a> ) and supplied as the only argument to <code>panel.error</code> . The default behaviour (implemented as the <code>panel.error</code> function) is to print the corresponding error message in the panel and continue. To stop execution on error, use <code>panel.error = stop</code> . Normal error recovery and debugging tools are unhelpful when <code>tryCatch</code> is used. <code>tryCatch</code> can be completely bypassed by setting <code>panel.error</code> to <code>NULL</code> .
<code>prefix</code>	A character string acting as a prefix identifying the plot of a "trellis" object, primarily used in constructing viewport and grob names, to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (specifically, "plot_01", "plot_02", etc.). If supplied explicitly, this must be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently " : ").
<code>e</code>	an error condition caught by <a href="#">tryCatch</a>
<code>...</code>	extra arguments, ignored by the <code>print</code> method. All arguments to the <code>plot</code> method are passed on to the <code>print</code> method.

## Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`.

When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see [trellis.focus](#).

## Note

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

        perm.cond,
        ...)

## S3 method for class 'trellis'
t(x)

## S3 method for class 'trellis'
x[i, j, ..., drop = FALSE]
```

```
trellis.last.object(..., prefix)
```

### Arguments

<code>object, x</code>	The object to be updated, of class "trellis".
<code>i, j</code>	indices to be used. Names are not currently allowed.
<code>drop</code>	logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were FALSE.
<code>panel, aspect, as.table, between, key, auto.key, legend, layout, main, page, par</code>	arguments that will be used to update <code>object</code> . See details below.
<code>prefix</code>	A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> .

### Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would needs to change the data within each panel is a no-no (this includes the `formula`, `data`, `groups`, `subscripts` and `subset`). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for [xyplot](#). Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The `"["` method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The `print` method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. By default, the last object plotted is retrieved, but if multiple objects are plotted on the current page, then others can be retrieved using the appropriate `prefix` argument. If [trellis.last.object](#) is called with arguments, these are used to update the retrieved object before returning it.

### Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns NULL if no saved object is available.

---

C\_07\_shingles

*shingles*

---

**Description**

Functions to handle shingles

**Usage**

```
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle'
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle'
print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel'
as.character(x, ...)

## S3 method for class 'shingleLevel'
print(x, ...)

## S3 method for class 'shingle'
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle'
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)
```

**Arguments**

<code>x</code>	numeric variable or R object, <code>shingle</code> in <code>plot.shingle</code> and <code>x[]</code> . An object (list of intervals) of class "shingleLevel" in <code>print.shingleLevel</code>
<code>object</code>	shingle object to be summarized
<code>showValues</code>	logical, whether to print the numeric part. If FALSE, only the intervals are printed
<code>intervals</code>	numeric vector or matrix with 2 columns
<code>subset</code>	logical vector
<code>drop</code>	whether redundant shingle levels are to be dropped
<code>panel, xlab, ylab</code>	standard Trellis arguments (see <a href="#">xyplot</a> )
<code>...</code>	other arguments, passed down as appropriate. For example, extra arguments to <code>equal.count</code> are passed on to <code>co.intervals</code> . graphical parameters can be passed as arguments to the <code>plot</code> method.

**Details**

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given `intervals`. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if `x` is not a shingle.

`is.shingle` tests whether `x` is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

**Value**

`x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.

D_draw.colorkey	<i>Produce a Colorkey for levelplot</i>
-----------------	---

---

**Description**

Produces (and possibly draws) a Grid frame grob which is a colorkey that can be placed in other Grid plots. Used in levelplot

**Usage**

```
draw.colorkey(key, draw=FALSE, vp=NULL)
```

**Arguments**

key	A list determining the key. See documentation for levelplot, in particular the section describing the colorkey argument, for details.
draw	logical, whether the grob is to be drawn.
vp	viewport

**Value**

A Grid frame object (that inherits from "grob")

**Author(s)**

D_draw.key	<i>Produce a Legend or Key</i>
------------	--------------------------------

---

**Description**

Produces (and possibly draws) a Grid frame grob which is a legend (aka key) that can be placed in other Grid plots.

**Usage**

```
draw.key(key, draw=FALSE, vp=NULL, ...)
```

**Arguments**

key	A list determining the key. See documentation for <code>xyplot</code> , in particular the section describing the <code>key</code> argument, for details.
draw	logical, whether the grob is to be drawn.
vp	viewport
...	ignored

**Value**

A Grid frame object (that inherits from ‘grob’).

---

D_level.colors	<i>A function to compute false colors representing a numeric or categorical variable</i>
----------------	--

---

**Description**

Calculates false colors from a numeric variable (including factors, using their numeric codes) given a color scheme and breakpoints.

**Usage**

```
level.colors(x, at, col.regions, colors = TRUE, ...)
```

**Arguments**

<code>x</code>	A numeric or <code>factor</code> variable.
<code>at</code>	A numeric variable of breakpoints defining intervals along the range of <code>x</code> .
<code>col.regions</code>	A specification of the colors to be assigned to each interval defined by <code>at</code> . This could be either a vector of colors, or a function that produces a vector of colors when called with a single argument giving the number of colors. See details below.
<code>colors</code>	logical indicating whether colors should be computed and returned. If <code>FALSE</code> , only the indices representing which interval (among those defined by <code>at</code> ) each value in <code>x</code> falls into is returned.
<code>...</code>	Extra arguments, ignored.

**Details**

If `at` has length `n`, then it defines `n-1` intervals. Values of `x` outside the range of `at` are not assigned to an interval, and the return value is `NA` for such values.

Colors are chosen by assigning a color to each of the `n-1` intervals. If `col.regions` is a palette function (such as `topo.colors`, or the result of calling `colorRampPalette`), it is called with `n-1` as an argument to obtain the colors. Otherwise, if there are exactly `n-1` colors in `col.regions`, these get assigned to the intervals. If there are fewer than `n-1` colors, `col.regions` gets recycled. If there are more, a more or less equally spaced (along the length of `col.regions`) subset is chosen.

**Value**

A vector of the same length as `x`. Depending on the `colors` argument, this could be either a vector of colors (in a form usable by `R`), or a vector of integer indices representing which interval the values of `x` fall in.

**Author(s)**

Deepayan Sarkar <deepayan.sarkar@r-project.org>

**Examples**

```
depth.col <-
  with(quakes,
    level.colors(depth, at = do.breaks(range(depth), 30),
      col.regions = terrain.colors))

xyplot(lat ~ long | equal.count(stations), quakes,
  strip = strip.custom(var.name = "Stations"),
  colours = depth.col,
  panel = function(x, y, colours, subscripts, ...) {
    panel.xyplot(x, y, pch = 21, col = "transparent",
      fill = colours[subscripts], ...)
  })
```

---

D\_make.groups

*Grouped data from multiple vectors*

---

### Description

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

### Usage

```
make.groups(...)
```

### Arguments

... one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

### Value

When all the input arguments are vectors, a data frame with two columns

data all the vectors supplied, concatenated

which factor indicating which vector the corresponding data value came from

When all the input arguments are data frames, the result of `rbind` applied to them, along with an additional `which` column as described above.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### Examples

```
sim.dat <-
  make.groups(uniform = runif(200),
             exponential = rexp(175),
             lognormal = rlnorm(150),
             normal = rnorm(125))
qqmath( ~ data | which, sim.dat, scales = list(y = "free"))
```

---

D\_simpleKey

Function to generate a simple key

---

## Description

Simple interface to generate a list appropriate for `draw.key`

## Usage

```
simpleKey(text, points = TRUE,
         rectangles = FALSE,
         lines = FALSE,
         col, cex, alpha, font,
         fontface, fontfamily,
         lineheight, ...)
```

## Arguments

<code>text</code>	character or expression vector, to be used as labels for levels of the grouping variable
<code>points</code>	logical
<code>rectangles</code>	logical
<code>lines</code>	logical
<code>col, cex, alpha, font, fontface, fontfamily, lineheight</code>	Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in <code>trellis.par.get("add.text")</code>
<code>...</code>	further arguments added to the list, eventually passed to <code>draw.key</code>

## Details

A lattice plot can include a legend (key) if an appropriate list is specified as the `key` argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at a cost: this list needs to be fairly complicated even in simple situations. `simpleKey` is designed as a useful shortcut in the common case of a key drawn in conjunction with a grouping variable, using the default graphical settings.

The `simpleKey` function produces a suitable `key` argument using a simpler interface. The resulting list will use the `text` argument as a text component, along with at most one set each of points, rectangles, and lines. The number of entries (rows) in the key will be the length of the `text` component. The graphical parameters for the additional components will be derived from the default graphical settings (wherein lies the simplification, as otherwise these would have to be provided explicitly).

Calling `simpleKey` directly is usually unnecessary. It is most commonly invoked (during the plotting of the "trellis" object) when the `auto.key` argument is supplied in a high-level plot with a `groups` argument. In that case, the `text` argument of `simpleKey` defaults to `levels(groups)`, and the defaults for the other arguments depend on the relevant high-level function. Note that these defaults can be overridden by supplying `auto.key` as a list containing the replacement values.

**Value**

A list that would work as the `key` argument to `xyplot`, etc.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

`Lattice`, `draw.key`, `trellis.par.get`, and `xyplot`, specifically the entry for `auto.key`.

---

D_strip.default	<i>Default Trellis Strip Function</i>
-----------------	---------------------------------------

---

**Description**

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

**Usage**

```
strip.default(which.given,
              which.panel,
              var.name,
              factor.levels,
              shingle.intervals,
              strip.names = c(FALSE, TRUE),
              strip.levels = c(TRUE, FALSE),
              sep = " : ",
              style = 1,
              horizontal = TRUE,
              bg = trellis.par.get("strip.background")$col[which.given],
              fg = trellis.par.get("strip.shingle")$col[which.given],
              par.strip.text = trellis.par.get("add.text"))
strip.custom(...)
```

**Arguments**

<code>which.given</code>	integer index specifying which of the conditioning variables this strip corresponds to.
<code>which.panel</code>	vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of <code>which.packet</code> , which is a more accurate name.
<code>var.name</code>	vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of <code>strip.names</code> and <code>style</code> (see below). By default, the names are shown for shingles, but not for factors.

<code>factor.levels</code>	vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with <code>which.given</code> . Whether these levels are shown on the strip depends on the values of <code>strip.levels</code> and <code>style</code> (see below). <code>factor.levels</code> may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in <code>par.strip.text</code> (see <code>xyplot</code> )
<code>shingle.intervals</code>	if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by <code>printing.levels(shingle)</code> ). Otherwise, it should be <code>NULL</code>
<code>strip.names</code>	a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when <code>style</code> is not one of 1 and 3.
<code>strip.levels</code>	a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.
<code>sep</code>	character or expression, serving as a separator if the name and level are both to be shown.
<code>style</code>	integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when <code>shingle.intervals</code> is non-null.  The best way to find out what effect the value of <code>style</code> has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.  Note that unlike S-PLUS, the default value of <code>style</code> is 1. <code>strip.names</code> and <code>strip.levels</code> have no effect if <code>style</code> is not 1 or 3.
<code>horizontal</code>	logical, specifying whether the labels etc should be horizontal. <code>horizontal=FALSE</code> is useful for strips on the left of panels using <code>strip.left=TRUE</code>
<code>par.strip.text</code>	list with parameters controlling the text on each strip, with components <code>col</code> , <code>cex</code> , <code>font</code> , etc.
<code>bg</code>	strip background color.
<code>fg</code>	strip foreground color.
<code>...</code>	arguments to be passed on to <code>strip.default</code> , overriding whatever value it would have normally assumed

**Details**

default strip function for trellis functions. Useful mostly because of the `style` argument — non-default styles are often more informative, especially when the names of the levels of the factor `x` are small. Traditional use is as `strip = function(...) strip.default(style=2,...)`, though this can be simplified by the use of `strip.custom`.

**Value**

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**Examples**

```
## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = function(..., style) strip.default(..., style = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = FALSE,
       strip.left = strip.custom(style = 4, horizontal = FALSE))
```

---

D\_trellis.object     *A Trellis Plot Object*

---

**Description**

This class of objects is returned by high level lattice functions, and is usually plotted by default by its [print](#) method.

**Details**

A trellis object, as returned by high level lattice functions like [xyplot](#), is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab` `ylab`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

`formula` the Trellis formula used in the call

`index.cond` list with index for each of the conditioning variables  
`perm.cond` permutation of the order of the conditioning variables  
`aspect.fill` logical, whether aspect is "fill"  
`aspect.ratio` numeric, aspect ratio to be used if `aspect.fill` is FALSE  
`call` call that generated the object.  
`condlevels` list with levels of the conditioning variables  
`legend` list describing the legend(s) to be drawn  
`panel.args` a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.  
`panel.args.common` a list containing the arguments common to all the panel functions in name=value form  
`x.scales` list describing x-scale, can consist of several other lists, paralleling `panel.args`, if x-relation is not "same"  
`y.scales` list describing y-scale, similar to `x.scales`  
`x.between` numeric vector of interpanel x-space  
`y.between` numeric vector of interpanel y-space  
`x.limits` numeric vector of length 2 or list, giving x-axis limits  
`y.limits` similar to `x.limits`  
`packet.sizes` array recording the number of observations in each packet

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### Description

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

**Usage**

```

panel.identify(x, y = NULL,
               subscripts = seq_along(x),
               labels = subscripts,
               n = length(x), offset = 0.5,
               threshold = 18, ## in points, roughly 0.25 inches
               panel.args = trellis.panelArgs(),
               ...)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
                     panel.args = trellis.panelArgs(),
                     ...)
panel.identify.cloud(x, y, z, subscripts,
                    perspective, distance,
                    xlim, ylim, zlim,
                    screen, R.mat, aspect, scales.3d,
                    ...,
                    panel.3d.identify,
                    n = length(subscripts),
                    offset = 0.5,
                    threshold = 18,
                    labels = subscripts,
                    panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
                        "figure", "panel", "strip", "strip.left",
                        "legend", "legend.region", "main", "sub",
                        "xlab", "ylab", "xlab.top", "ylab.right", "page"),
               column, row,
               side = c("left", "top", "right", "bottom", "inside"),
               clip.off = FALSE, prefix)
trellis.grobname(name,
                 type = c("", "panel", "strip", "strip.left",
                           "key", "colorkey"),
                 group = 0,
                 which.given = lattice.getStatus("current.which.given",
                                                  prefix = prefix),
                 which.panel = lattice.getStatus("current.which.panel",
                                                  prefix = prefix),
                 column = lattice.getStatus("current.focus.column",
                                            prefix = prefix),
                 row = lattice.getStatus("current.focus.row",
                                         prefix = prefix),
                 prefix = lattice.getStatus("current.prefix"))
trellis.focus(name, column, row, side, clip.off,
              highlight = interactive(), ..., prefix,
              guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ..., prefix)
trellis.unfocus()
trellis.panelArgs(x, packet.number)

```

**Arguments**

<code>x, y, z</code>	variables defining the contents of the panel. In the case of <code>trellis.panelArgs</code> , a "trellis" object.
<code>n</code>	the number of points to identify by default (overridden by a right click)
<code>subscripts</code>	an optional vector of integer indices associated with each point. See details below.
<code>labels</code>	an optional vector of labels associated with each point. Defaults to <code>subscripts</code>
<code>distribution, groups</code>	typical panel arguments of <code>panel.qqmath</code> . These will usually be obtained from <code>panel.args</code>
<code>offset</code>	the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The <code>offset</code> specifies (in "char" units) how far from the identified point the labels should be printed.
<code>threshold</code>	threshold in grid's "points" units. Points further than these from the mouse click position are not considered
<code>panel.args</code>	list that contains components names <code>x</code> (and usually <code>y</code> ), to be used if <code>x</code> is missing. Typically, when called after <code>trellis.focus</code> , this would appropriately be the arguments passed to that panel.
<code>perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d</code>	arguments as passed to <code>panel.cloud</code> . These are required to recompute the relevant three-dimensional projections in <code>panel.identify.cloud</code> .
<code>panel.3d.identify</code>	the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to <code>panel.identify</code> is used.
<code>name</code>	<p>A character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most of the ones that end-users may find interesting. <code>trellis.vpname</code> and <code>trellis.focus</code> deal with viewport names only, and only accept the values explicitly listed above. <code>trellis.grobname</code> is meant to create names for grobs, and can currently accept any value.</p> <p>If <code>name</code>, as well as <code>column</code> and <code>row</code> is missing in a call to <code>trellis.focus</code>, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.</p> <p>When <code>name</code> is "panel", "strip", or "strip.left", <code>column</code> and <code>row</code> must also be specified. When <code>name</code> is "legend", <code>side</code> must also be specified.</p>
<code>column, row</code>	integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with <code>as.table=TRUE</code>
<code>guess</code>	logical. If <code>TRUE</code> , and the display has only one panel, that panel will be automatically selected by a call to <code>trellis.focus</code> .
<code>side</code>	character string, relevant only for legends (i.e., when <code>name="legend"</code> ), indicating their position. Partial specification is allowed, as long as it is unambiguous.

<code>clip.off</code>	logical, whether clipping should be off, relevant when name is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting <code>clip.off=FALSE</code> does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.
<code>type</code>	A character string specifying whether the grob is specific to a particular panel or strip. When <code>type</code> is "panel", "strip", or "strip.left", information about the panel is added to the grob name.
<code>group</code>	An integer specifying whether the grob is specific to a particular group within the plot. When <code>group</code> is greater than zero, information about the group is added to the grob name.
<code>which.given,</code> <code>which.panel</code>	integers, indicating which conditional variable is being represented (within a strip) and the current levels of the conditional variables. When <code>which.panel</code> has length greater than 1, and the <code>type</code> is "strip" or "strip.left", information about the conditional variable is added to the grob name.
<code>prefix</code>	A character string acting as a prefix identifying the plot of a "trellis" object, primarily used to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the <code>prefix</code> argument in <code>print.trellis</code> . Users should not usually need to supply a value for this argument except to interact with an existing plot other than the one plotted last. For <code>switchFocus</code> , ignored except when it does not match the prefix of the currently active plot, in which case an error occurs.
<code>highlight</code>	logical, whether the viewport being assigned focus should be highlighted. For <code>trellis.focus</code> , the default is TRUE in interactive mode, and <code>trellis.switchFocus</code> by default preserves the setting currently active.
<code>packet.number</code>	integer, which panel to get data from. See <code>packet.number</code> for details on how this is calculated
<code>verbose</code>	whether details will be printed
<code>...</code>	For <code>panel.identify.qqmath</code> , extra parameters are passed on to <code>panel.identify</code> . For <code>panel.identify</code> , extra arguments are treated as graphical parameters and are used for labelling. For <code>trellis.focus</code> and <code>trellis.switchFocus</code> , these are used (in combination with <code>lattice.options</code> ) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for <code>panel.link.splom</code> .

## Details

`panel.identify` is similar to `identify`. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with `splom`, and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `qqmath`. `panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `cloud`. It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`, but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the `subscripts` that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the `name` along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the 'current' viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current `row` and `column`. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the `panel` entry in `xyplot`) and not the position in the layout, because a layout determines the panel only **after** the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

**Value**

`panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.

`trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.

`trellis.vpname` and `trellis.grobname` return character strings.

`trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

**Note**

The viewports created by `lattice` are accessible to the user through `trellis.focus` as described above. Functions from the `grid` package can also be used directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` provides a portable way to access the appropriate viewports and grobs by name.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>. Felix Andrews provided initial implementations of `panel.identify`, `qqmath` and support for focusing on panels interactively.

      trellis.unfocus()
      i <- i + 1
    }

```

## Description

Default panel function for barchart.

## Usage

```
panel.barchart(x, y, box.ratio = 1, box.width,
               horizontal = TRUE,
               origin = NULL, reference = TRUE,
               stack = FALSE,
               groups = NULL,
               col = if (is.null(groups)) plot.polygon$col
                     else superpose.polygon$col,
               border = if (is.null(groups)) plot.polygon$border
                     else superpose.polygon$border,
               lty = if (is.null(groups)) plot.polygon$lty
                     else superpose.polygon$lty,
               lwd = if (is.null(groups)) plot.polygon$lwd
                     else superpose.polygon$lwd,
               ..., identifier = "barchart")
```

## Arguments

<code>x</code>	Extent of Bars. By default, bars start at left of panel, unless <code>origin</code> is specified, in which case they start there.
<code>y</code>	Horizontal location of bars. Possibly a factor.
<code>box.ratio</code>	Ratio of bar width to inter-bar space.
<code>box.width</code>	Thickness of bars in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
<code>horizontal</code>	Logical flag. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.
<code>origin</code>	The origin for the bars. For grouped displays with <code>stack = TRUE</code> , this argument is ignored and the origin set to 0. Otherwise, defaults to <code>NULL</code> , in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, <code>origin = 0</code> is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).
<code>reference</code>	Logical, whether a reference line is to be drawn at the origin.
<code>stack</code>	logical, relevant when <code>groups</code> is non-null. If <code>FALSE</code> (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.
<code>groups</code>	Optional grouping variable.
<code>col, border, lty, lwd</code>	Graphical parameters for the bars. By default, the trellis parameter <code>plot.polygon</code> is used if there is no grouping variable, otherwise <code>superpose.polygon</code> is used. <code>col</code> gives the fill color, <code>border</code> the border color, and <code>lty</code> and <code>lwd</code> the line type and width of the borders.
<code>...</code>	Extra arguments will be accepted but ignored.

`identifier` A character string that is prepended to the names of grobs that are created by this panel function.

### Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level `barchart` call directly.

### Examples

```
barchart(yield ~ variety | site, data = barley,
         groups = year, layout = c(1,6), origin = 0,
         ylab = "Barley Yield (bushels/acre)",
         scales = list(x = list(abbreviate = TRUE,
                                minlength = 5)))
```

---

F_1_panel.bwplot	<i>Default Panel Function for bwplot</i>
------------------	--

---

### Description

This is the default panel function for `bwplot`.

### Usage

```
panel.bwplot(x, y, box.ratio = 1,
             box.width = box.ratio / (1 + box.ratio),
             horizontal = TRUE,
             pch, col, alpha, cex,
             font, fontfamily, fontface,
             fill, varwidth = FALSE,
             notch = FALSE, notch.frac = 0.5,
             ...,
             levels.fos,
             stats = boxplot.stats,
             coef = 1.5,
             do.out = TRUE,
             identifier = "bwplot")
```

**Arguments**

<code>x, y</code>	numeric vector or factor. Boxplots drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )
<code>box.ratio</code>	ratio of box thickness to inter box space
<code>box.width</code>	thickness of box in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is 'transposed' in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.
<code>pch, col, alpha, cex, font, fontfamily, fontface</code>	graphical parameters controlling the dot. <code>pch=" "</code> is treated specially, by replacing the dot with a line (similar to <a href="#">boxplot</a> )
<code>fill</code>	color to fill the boxplot
<code>varwidth</code>	logical. If <code>TRUE</code> , widths of boxplots are proportional to the number of points used in creating it.
<code>notch</code>	if <code>notch</code> is <code>TRUE</code> , a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers et al., 1983, p. 62). See <a href="#">boxplot.stats</a> for the calculations used.
<code>notch.frac</code>	numeric in (0,1). When <code>notch=TRUE</code> , the fraction of the box width that the notches should use.
<code>stats</code>	a function, defaulting to <a href="#">boxplot.stats</a> , that accepts a numeric vector and returns a list similar to the return value of <code>boxplot.stats</code> . The function must accept arguments <code>coef</code> and <code>do.out</code> even if they do not use them (a <code>...</code> argument is good enough). This function is used to determine the box and whisker plot.
<code>coef, do.out</code>	passed to <code>stats</code>
<code>levels.fos</code>	numeric values corresponding to positions of the factor or shingle variable. For internal use.
<code>...</code>	further arguments, ignored.
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

**Details**

Creates Box and Whisker plot of `x` for every level of `y` (or the other way round if `horizontal=FALSE`). By default, the actual boxplot statistics are calculated using `boxplot.stats`. Note that most arguments controlling the display can be supplied to the high-level `bwplot` call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("`box.rectangle`" for the box, "`box.umbrella`" for the whiskers and "`plot.symbol`" for the outliers).

            alpha.regions = regions$alpha,
            identifier = "3dwire")

```

### Arguments

<code>x, y, z</code>	<p>numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For <code>panel.cloud</code> these are essentially the same as the data passed to the high level plot (except if <code>formula</code> was a matrix, the appropriate <code>x</code> and <code>y</code> vectors are generated). By the time they are passed to <code>panel.3dscatter</code> and <code>panel.3dwire</code>, they have been appropriately subsetting (using <code>subscripts</code>) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube).</p> <p>Further, for <code>panel.3dwire</code>, <code>x</code> and <code>y</code> are shorter than <code>z</code> and represent the sorted locations defining a rectangular grid. Also in this case, <code>z</code> may be a matrix if the display is grouped, with each column representing one surface.</p> <p>In <code>panel.cloud</code> (called from <code>wireframe</code>) and <code>panel.3dwire</code>, <code>x</code>, <code>y</code> and <code>z</code> could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.</p>
<code>subscripts</code>	index specifying which points to draw. The same <code>x</code> , <code>y</code> and <code>z</code> values (representing the whole data) are passed to <code>panel.cloud</code> for each panel. <code>subscripts</code> specifies the subset of rows to be used for the particular panel.
<code>groups</code>	specification of a grouping variable, passed down from the high level functions.
<code>perspective</code>	logical, whether to plot a perspective view. Setting this to <code>FALSE</code> is equivalent to setting <code>distance</code> to 0
<code>distance</code>	numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is $1 / \text{distance}$ . This is described in a little more detail in the documentation for <a href="#">cloud</a>

<code>screen</code>	A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive z-axis, and the x and y axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.
<code>R.mat</code>	initial rotation matrix in homogeneous coordinates, to be applied to the data before <code>screen</code> rotates the view further.
<code>par.box</code>	graphical parameters for box, namely, col, lty and lwd. By default obtained from the parameter <code>box.3d</code> .
<code>xlim, ylim, zlim</code>	limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.
<code>panel.3d.cloud, panel.3d.wireframe</code>	functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in <code>cloud</code> and <code>wireframe</code> . This function is called after the 'back' of the bounding box is drawn, but before the 'front' is drawn. Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called <code>xlim</code> , <code>ylim</code> , <code>zlim</code> which give the bounding box ranges in the original data scale and <code>xlim.scaled</code> , <code>ylim.scaled</code> , <code>zlim.scaled</code> which give the bounding box ranges in the transformed scale. More arguments can be considered on request.
<code>aspect</code>	aspect as in <code>cloud</code>
<code>xlab, ylab, zlab</code>	Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to <code>cloud</code> directly.
<code>xlab.default</code>	for internal use
<code>ylab.default</code>	for internal use
<code>zlab.default</code>	for internal use
<code>scales.3d</code>	list defining the scales
<code>proportion</code>	numeric scalar, gives the length of arrows as a proportion of the sides
<code>scpos</code>	A list with three components x, y and z (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are x: 1, 3, 9, 11; y: 8, 5, 7, 6 and z: 4, 2, 10, 12. (See comments in the source code of <code>panel.cloud</code> to see the details of this enumeration.)
<code>wireframe</code>	logical, indicating whether this is a wireframe plot
<code>drape</code>	logical, whether the facets will be colored by height, in a manner similar to <code>levelplot</code> . This is ignored if <code>shade=TRUE</code> .
<code>at, col.regions, alpha.regions</code>	deals with specification of colors when <code>drape = TRUE</code> in <code>wireframe</code> . <code>at</code> can be a numeric vector, <code>col.regions</code> a vector of colors, and <code>alpha.regions</code> a numeric scalar controlling transparency. The resulting behaviour is similar to <code>levelplot</code> , <code>at</code> giving the breakpoints along the z-axis where colors change, and the other two determining the colors of the facets that fall in between.
<code>rot.mat</code>	4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the <code>screen</code> and <code>R.mat</code> arguments to <code>panel.cloud</code>

<code>type</code>	Character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean 'points' and 'lines' respectively, and "b" means 'both'. "h" stands for 'histogram', and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing $z = 0$ ), or the lower (or upper) bounding box face, whichever is closer.
<code>xlim.scaled, ylim.scaled, zlim.scaled</code>	axis limits (after being scaled to the bounding box)
<code>zero.scaled</code>	z-axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when <code>type = "h"</code>
<code>cross</code>	logical, defaults to TRUE if <code>pch = "+"</code> . <code>panel.3dscatter</code> can represent each point by a 3d 'cross' of sorts (it's much easier to understand looking at an example than from a description). This is different from the usual <code>pch</code> argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.  This is useful for two reasons. It can be set to FALSE to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.
<code>shade</code>	logical, indicating whether the surface is to be colored using an illumination model with a single light source
<code>shade.colors.palette</code>	a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits.  All three numbers should be between 0 and 1. The <code>shade.colors.palette</code> function should return a valid color. The default function is obtained from the trellis settings.
<code>light.source</code>	a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube
<code>polynum</code>	quadrilateral faces are drawn in batches of <code>polynum</code> at a time. Drawing too few at a time increases the total number of calls to the underlying <code>grid.polygon</code> function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.
<code>col.groups</code>	colors for different groups
<code>col, col.point, col.line, lty, lwd, cex, pch, alpha</code>	Graphical parameters. Some other arguments (such as <code>lex</code> for line width) may also be passed through the ... argument.
<code>...</code>	other parameters, passed down when appropriate
<code>.scale</code>	Logical flag, indicating whether x, y, and z should be assumed to be in the original data scale and hence scaled before being plotted. x, y, and z are usually already scaled. However, setting <code>.scale=TRUE</code> may be helpful for calls to <code>panel.3dscatter</code> and <code>panel.3dwire</code> in user-supplied panel functions.
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

## Details

These functions together are responsible for the content drawn inside each panel in `cloud` and `wireframe`. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work.

`panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is `TRUE`, it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For `cloud`, the data is unstructured, and `x`, `y` and `z` are all passed to the `panel.3d.cloud` function. For `wireframe`, on the other hand, `x` and `y` are increasing vectors with unique values, defining a rectangular grid. `z` must be a matrix with `length(x) * length(y)` rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a `type` argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `polynum` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly, speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source.palette.shade` is a simple function that provides the default shading colors

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

`F_1_panel.densityplot`

*Default Panel Function for densityplot*

---

## Description

This is the default panel function for `densityplot`.

## Usage

```
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
                  groups = NULL, weights = NULL,
                  jitter.amount, type, ...,
                  identifier = "density")
```

**Arguments**

<code>x</code>	data points for which density is to be estimated
<code>darg</code>	list of arguments to be passed to the <code>density</code> function. Typically, this should be a list with zero or more of the following components : <code>bw</code> , <code>adjust</code> , <code>kernel</code> , <code>window</code> , <code>width</code> , <code>give.Rkern</code> , <code>n</code> , <code>from</code> , <code>to</code> , <code>cut</code> , <code>na.rm</code> (see <a href="#">density</a> for details)
<code>plot.points</code>	logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are <code>"rug"</code> , in which case <a href="#">panel.rug</a> is used to plot a ‘rug’, and <code>"jitter"</code> , in which case the points are jittered vertically to better distinguish overlapping points.
<code>ref</code>	logical, whether to draw x-axis
<code>groups</code>	an optional grouping variable. If present, <a href="#">panel.superpose</a> will be used instead to display each subgroup
<code>weights</code>	numeric vector of weights for the density calculations. If this is specified, the <code>...</code> part must also include a <code>subscripts</code> argument that matches the weights to <code>x</code> .
<code>jitter.amount</code>	when <code>plot.points="jitter"</code> , the value to use as the <code>amount</code> argument to <a href="#">jitter</a> .
<code>type</code>	type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a <code>type</code> argument, if specified, from affecting the density curve.
<code>...</code>	extra graphical parameters. Note that additional arguments to <a href="#">panel.rug</a> cannot be passed on through <code>panel.densityplot</code> .
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

`F_1_panel.dotplot`    *Default Panel Function for dotplot*

---

**Description**

Default panel function for `dotplot`.

**Usage**

```
panel.dotplot(x, y, horizontal = TRUE,
              pch, col, lty, lwd,
              col.line, levels.fos,
              groups = NULL,
              ...,
              identifier = "dotplot")
```

**Arguments**

<code>x, y</code>	variables to be plotted in the panel. Typically <code>y</code> is the ‘factor’
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <a href="#">bwplot</a> for a fuller explanation.
<code>pch, col, lty, lwd, col.line</code>	graphical parameters
<code>levels.fos</code>	locations where reference lines will be drawn
<code>groups</code>	grouping variable (affects graphical parameters)
<code>...</code>	extra parameters, passed to <code>panel.xyplot</code> which is responsible for drawing the foreground points ( <code>panel.dotplot</code> only draws the background reference lines).
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

**Details**

Creates (possibly grouped) Dotplot of `x` against `y` or vice versa

F\_1\_panel.histogram

*Default Panel Function for histogram*

---

**Description**

This is the default panel function for `histogram`.

**Usage**

```
panel.histogram(x,
               breaks,
               equal.widths = TRUE,
               type = "density",
               nint = round(log2(length(x)) + 1),
               alpha, col, border, lty, lwd,
               ...,
               identifier = "histogram")
```

**Arguments**

<code>x</code>	The data points for which the histogram is to be drawn
<code>breaks</code>	The breakpoints for the histogram
<code>equal.widths</code>	logical used when <code>breaks==NULL</code>
<code>type</code>	Type of histogram, possible values being "percent", "density" and "count"
<code>nint</code>	Number of bins for the histogram
<code>alpha, col, border, lty, lwd</code>	graphical parameters for bars; defaults are obtained from the <code>plot.polygon</code> settings.
<code>...</code>	other arguments, passed to <code>hist</code> when deemed appropriate
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

F\_1\_panel.levelplot

*Panel Functions for levelplot and contourplot*

---

**Description**

These are the default panel functions for `levelplot` and `contourplot`. Also documented is an alternative raster-based panel function for use with `levelplot`.

**Usage**

```
panel.levelplot(x, y, z,
                subscripts,
                at = pretty(z),
                shrink,
                labels,
                label.style = c("mixed", "flat", "align"),
                contour = FALSE,
                region = TRUE,
                col = add.line$col,
                lty = add.line$lty,
                lwd = add.line$lwd,
                border = "transparent",
                border.lty = 1,
                border.lwd = 0.1,
                ...,
                col.regions = regions$col,
```

```

        alpha.regions = regions$alpha,
        identifier = "levelplot")
panel.contourplot(...)

panel.levelplot.raster(x, y, z,
                      subscripts,
                      at = pretty(z),
                      ...,
                      col.regions = regions$col,
                      alpha.regions = regions$alpha,
                      interpolate = FALSE,
                      identifier = "levelplot")

```

### Arguments

<code>x, y, z</code>	Variables defining the plot.
<code>subscripts</code>	Integer vector indicating what subset of <code>x</code> , <code>y</code> and <code>z</code> to draw.
<code>at</code>	Numeric vector giving breakpoints along the range of <code>z</code> . See <a href="#">levelplot</a> for details.
<code>shrink</code>	Either a numeric vector of length 2 (meant to work as both <code>x</code> and <code>y</code> components), or a list with components <code>x</code> and <code>y</code> which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the <code>z</code> -value. The specification can be made separately for widths ( <code>x</code> ) and heights ( <code>y</code> ). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of <code>z</code> ).
<code>labels</code>	Either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the <code>at</code> values. Alternatively, <code>labels</code> can be a list with the following components:  <code>labels</code> : a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used. <code>col, cex, alpha</code> : graphical parameters for label texts <code>fontfamily, fontface, font</code> : font used for the labels
<code>label.style</code>	Controls how label positions and rotation are determined. A value of <code>"flat"</code> causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of <code>"align"</code> causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.
<code>contour</code>	A logical flag, specifying whether contour lines should be drawn.
<code>region</code>	A logical flag, specifying whether inter-contour regions should be filled with appropriately colored rectangles.
<code>col, lty, lwd</code>	Graphical parameters for contour lines.
<code>border</code>	Border color for rectangles used when <code>region=TRUE</code> .
<code>border.lty, border.lwd</code>	Graphical parameters for the border

<code>...</code>	Extra parameters.
<code>col.regions</code>	A vector of colors, or a function to produce a vector of colors, to be used if <code>region=TRUE</code> . Each interval defined by <code>at</code> is assigned a color, so the number of colors actually used is one less than the length of <code>at</code> . See <a href="#">level.colors</a> for details on how the color assignment is done.
<code>alpha.regions</code>	numeric scalar controlling transparency of facets
<code>interpolate</code>	logical, passed to <a href="#">grid.raster</a> .
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

## Details

The same panel function is used for both `levelplot` and `contourplot` (which differ only in default values of some arguments). `panel.contourplot` is a simple wrapper to `panel.levelplot`.

When `contour=TRUE`, the `contourLines` function is used to calculate the contour lines.

`panel.levelplot.raster` is an alternative panel function that uses the raster drawing abilities in R 2.11.0 and higher (through [grid.raster](#)). It has fewer options (e.g., can only render data on an equispaced grid), but can be more efficient. When using `panel.levelplot.raster`, it may be desirable to render the color key in the same way. This is possible, but must be done separately; see [levelplot](#) for details.

F_1_panel.pairs	<i>Default Superpanel Function for splom</i>
-----------------	--

---

## Description

This is the default superpanel function for splom.

## Usage

```
panel.pairs(z,
            panel = lattice.getOption("panel.splom"),
            lower.panel = panel,
            upper.panel = panel,
            diag.panel = "diag.panel.splom",
            as.matrix = FALSE,
            groups = NULL,
            panel.subscripts,
            subscripts,
            pscales = 5,
            prepanel.limits = scale.limits,
            varnames = colnames(z),
            varname.col, varname.cex, varname.font,
            varname.fontfamily, varname.fontface,
            axis.text.col, axis.text.cex, axis.text.font,
            axis.text.fontfamily, axis.text.fontface,
            axis.text.lineheight,
            axis.line.col, axis.line.lty, axis.line.lwd,
            axis.line.alpha, axis.line.tck,
            ...)
diag.panel.splom(x = NULL,
                 varname = NULL, limits, at = NULL, labels = NULL,
                 draw = TRUE, tick.number = 5,
                 varname.col, varname.cex,
                 varname.lineheight, varname.font,
                 varname.fontfamily, varname.fontface,
                 axis.text.col, axis.text.alpha,
                 axis.text.cex, axis.text.font,
                 axis.text.fontfamily, axis.text.fontface,
                 axis.text.lineheight,
                 axis.line.col, axis.line.alpha,
                 axis.line.lty, axis.line.lwd,
                 axis.line.tck,
                 ...)
```

## Arguments

**z** The data frame used for the plot.

**panel, lower.panel, upper.panel** The panel function used to display each pair of variables. If specified, lower.panel and upper.panel are used for panels below and above the diagonal respectively.

	In addition to extra arguments not recognized by <code>panel.pairs</code> , the list of arguments passed to the panel function also includes arguments named <code>i</code> and <code>j</code> , with values indicating the row and column of the scatterplot matrix being plotted.
<code>diag.panel</code>	The panel function used for the diagonals. See arguments to <code>diag.panel.splom</code> to know what arguments this function is passed when called.
<code>as.matrix</code>	logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to <code>pairs</code> ). This is in essence the same functionality as provided by <code>as.table</code> for the panel layout
<code>groups</code>	Grouping variable, if any
<code>panel.subscripts</code>	logical specifying whether the panel function accepts an argument named <code>subscripts</code> .
<code>subscripts</code>	The indices of the rows of <code>z</code> that are to be displayed in this (super)panel.
<code>pscales</code>	Controls axis labels, passed down from <code>splom</code> . If <code>pscales</code> is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If <code>pscales</code> is a list, it should have one component for each column in <code>z</code> , each of which itself a list with the following valid components: <code>at</code> : a numeric vector specifying tick locations <code>labels</code> : character vector labels to go with <code>at</code> <code>limits</code> : numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors) These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use <code>pscales=0</code> to suppress the axes entirely.
<code>prepanel.limits</code>	A function to calculate suitable axis limits given a single argument <code>x</code> containing a data vector. The return value of the function should be similar to the <code>xlim</code> or <code>ylim</code> argument documented in <code>xyplot</code> ; that is, it should be a numeric or DateTime vector of length 2 defining a range, or a character vector representing levels of a factor. Most high-level lattice plots (such as <code>xyplot</code> ) use the <code>prepanel</code> function for deciding on axis limits from data. This function serves a similar function by calculating the per-variable limits. These limits can be overridden by the corresponding <code>limits</code> component in the <code>pscales</code> list.
<code>x</code>	data vector corresponding to that row / column (which will be the same for diagonal 'panels').
<code>varname</code>	(scalar) character string or expression that is to be written centred within the panel
<code>limits</code>	numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)
<code>at</code>	locations of tick marks
<code>labels</code>	optional labels for tick marks
<code>draw</code>	A logical flag specifying whether to draw the tick marks and labels. If FALSE, variable names are shown but axis annotation is omitted.
<code>tick.number</code>	A Numeric scalar giving the suggested number of tick marks.

<code>varnames</code>	A character or expression vector or giving names to be used for the variables in <code>x</code> . By default, the column names of <code>x</code> .
<code>varname.col</code>	Color for the variable name in each diagonal panel. See <a href="#">gpar</a> for details on this and the other graphical parameters listed below.
<code>varname.cex</code>	Size multiplier for the variable name in each diagonal panel.
<code>varname.lineheight</code>	Line height for the variable name in each diagonal panel.
<code>varname.font</code> , <code>varname.fontfamily</code> , <code>varname.fontface</code>	Font specification for the variable name in each diagonal panel.
<code>axis.text.col</code>	Color for axis label text.
<code>axis.text.cex</code>	Size multiplier for axis label text.
<code>axis.text.font</code> , <code>axis.text.fontfamily</code> , <code>axis.text.fontface</code>	Font specification for axis label text.
<code>axis.text.lineheight</code>	Line height for axis label text.
<code>axis.text.alpha</code>	Alpha-transparency for axis label text.
<code>axis.line.col</code>	Color for the axes.
<code>axis.line.lty</code>	Line type for the axes.
<code>axis.line.lwd</code>	Line width for the axes.
<code>axis.line.alpha</code>	Alpha-transparency for the axes.
<code>axis.line.tck</code>	A numeric multiplier for the length of tick marks in diagonal panels.
<code>...</code>	Further arguments, passed on to <code>panel</code> , <code>lower.panel</code> , <code>upper.panel</code> , and <code>diag.panel</code> from <code>panel.pairs</code> . Currently ignored by <code>diag.panel.splom</code> .

### Details

`panel.pairs` is the function that is actually used as the `panel` function in a "trellis" object produced by `splom`.

## Examples

```
Cmat <- outer(1:6,1:6,
             function(i,j) rainbow(11, start=.12, end=.5)[i+j-1])

splom(~diag(6), as.matrix = TRUE,
      panel = function(x, y, i, j, ...) {
        panel.fill(Cmat[i,j])
        panel.text(.5,.5, paste("(",i,",",j,")",sep=""))
      })
```

---

F\_1\_panel.parallel *Default Panel Function for parallel*

---

## Description

This is the default panel function for parallel.

## Usage

```
panel.parallel(x, y, z, subscripts,
              groups = NULL,
              col, lwd, lty, alpha,
              common.scale = FALSE,
              lower,
              upper,
              ...,
              horizontal.axis = TRUE,
              identifier = "parallel")
```

## Arguments

<code>x, y</code>	dummy variables, ignored.
<code>z</code>	The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.
<code>subscripts</code>	The indices of the rows of <code>z</code> that are to be displayed in this panel.
<code>groups</code>	An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of <code>z</code> in the same group share parameters).
<code>col, lwd, lty, alpha</code>	graphical parameters (defaults to the settings for <code>superpose.line</code> ). If <code>groups</code> is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame <code>z</code> .
<code>common.scale</code>	logical, whether a common scale should be used columns of <code>z</code> . Defaults to <code>FALSE</code> , in which case the horizontal range for each column is different (as determined by <code>lower</code> and <code>upper</code> ).
<code>lower, upper</code>	numeric vectors replicated to be as long as the number of columns in <code>z</code> . Determines the lower and upper bounds to be used for scaling the corresponding columns of <code>z</code> after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.

...	other arguments (ignored)
horizontal.axis	logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
identifier	A character string that is prepended to the names of grobs that are created by this panel function.

### Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for [parallel](#)

F_1_panel.qqmath	<i>Default Panel Function for qqmath</i>
------------------	--

---

### Description

This is the default panel function for qqmath.

### Usage

```
panel.qqmath(x, f.value = NULL,
             distribution = qnorm,
             qtype = 7,
             groups = NULL, ...,
             tails.n = 0,
             identifier = "qqmath")
```

### Arguments

x	vector (typically numeric, coerced if not) of data values to be used in the panel.
f.value, distribution	Defines how quantiles are calculated. See <a href="#">qqmath</a> for details.
qtype	The type argument to be used in <a href="#">quantile</a>
groups	An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.

...	Further arguments, often graphical parameters, eventually passed on to <a href="#">panel.xyplot</a> . Arguments <code>grid</code> and <code>abline</code> of <code>panel.xyplot</code> may be particularly useful.
<code>tails.n</code>	number of data points to represent exactly on each tail of the distribution. This reproduces the effect of <code>f.value = NULL</code> for the extreme data values, while approximating the remaining data. It has no effect if <code>f.value = NULL</code> . If <code>tails.n</code> is given, <code>qtype</code> is forced to be 1.
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

### Details

Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### Examples

```
set.seed(0)
xx <- rt(10000, df = 10)
qqmath(~ xx, pch = "+", distribution = qnorm,
       grid = TRUE, abline = c(0, 1),
       xlab.top = c("raw", "ppoints(100)", "tails.n = 50"),
       panel = function(..., f.value) {
         switch(panel.number(),
               panel.qqmath(..., f.value = NULL),
               panel.qqmath(..., f.value = ppoints(100)),
               panel.qqmath(..., f.value = ppoints(100), tails.n = 50))
       }, layout = c(3, 1))[c(1,1,1)]
```

---

F\_1\_panel.stripplot

*Default Panel Function for stripplot*

---

### Description

This is the default panel function for `stripplot`. Also see `panel.superpose`

### Usage

```
panel.stripplot(x, y, jitter.data = FALSE,
               factor = 0.5, amount = NULL,
               horizontal = TRUE, groups = NULL,
               ...,
               identifier = "stripplot")
```

**Arguments**

<code>x, y</code>	coordinates of points to be plotted
<code>jitter.data</code>	whether points should be jittered to avoid overplotting. The actual jittering is performed inside <code>panel.xyplot</code> , using its <code>jitter.x</code> or <code>jitter.y</code> argument (depending on the value of <code>horizontal</code> ).
<code>factor, amount</code>	amount of jittering, see <code>jitter</code>
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
<code>groups</code>	optional grouping variable
<code>...</code>	additional arguments, passed on to <code>panel.xyplot</code>
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

**Details**

Creates stripplot (one dimensional scatterplot) of `x` for each level of `y` (or vice versa, depending on the value of `horizontal`)

---

<code>F_1_panel.xyplot</code>	<i>Default Panel Function for xyplot</i>
-------------------------------	--

---

**Description**

This is the default panel function for `xyplot`. Also see `panel.superpose`. The default panel functions for `splo`m and `qq` are essentially the same function.

**Usage**

```
panel.xyplot(x, y, type = "p",
             groups = NULL,
             pch, col, col.line, col.symbol,
             font, fontfamily, fontface,
             lty, cex, fill, lwd,
             horizontal = FALSE, ...,
             grid = FALSE, abline = NULL,
             jitter.x = FALSE, jitter.y = FALSE,
             factor = 0.5, amount = NULL,
             identifier = "xyplot")
panel.splo(m(..., identifier = "splo(m)")
panel.qq(..., identifier = "qq")
```

**Arguments**

<code>x, y</code>	variables to be plotted in the scatterplot
<code>type</code>	<p>character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth", and "spline". If <code>type</code> has more than one element, an attempt is made to combine the effect of each of the components.</p> <p>The behaviour if any of the first six are included in <code>type</code> is similar to the effect of <code>type</code> in <code>plot</code> (<code>type</code> "b" is actually the same as "o"). "r" adds a linear regression line (same as <code>panel.lmline</code>, except for default graphical parameters). "smooth" adds a loess fit (same as <code>panel.loess</code>). "spline" adds a cubic smoothing spline fit (same as <code>panel.spline</code>). "g" adds a reference grid using <code>panel.grid</code> in the background (but using the <code>grid</code> argument is now the preferred way to do so). "a" has the effect of calling <code>panel.average</code>, which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of <code>horizontal</code>.</p> <p>Type "s" (and "S") sorts the values along one of the axes (depending on <code>horizontal</code>); this is unlike the behavior in <code>plot</code>. For the latter behavior, use <code>type = "s"</code> with <code>panel = panel.points</code>.</p> <p>See <code>example(xyplot)</code> and <code>demo(lattice)</code> for examples.</p>
<code>groups</code>	an optional grouping variable. If present, <code>panel.superpose</code> will be used instead to display each subgroup
<code>col, col.line, col.symbol</code>	default colours are obtained from <code>plot.symbol</code> and <code>plot.line</code> using <code>trellis.par.get</code> .
<code>font, fontface, fontfamily</code>	font used when <code>pch</code> is a character
<code>pch, lty, cex, lwd, fill</code>	other graphical parameters. <code>fill</code> serves the purpose of <code>bg</code> in <code>points</code> for certain values of <code>pch</code>
<code>horizontal</code>	A logical flag controlling the orientation for certain <code>type</code> 's, e.g., "h", "s", and "S".
<code>...</code>	Extra arguments, if any, for <code>panel.xyplot</code> . In most cases <code>panel.xyplot</code> ignores these. For types "r" and "smooth", these are passed on to <code>panel.lmline</code> and <code>panel.loess</code> respectively.
<code>grid</code>	<p>A logical flag, character string, or list specifying whether and how a background grid should be drawn. This provides the same functionality as <code>type="g"</code>, but is the preferred alternative as the effect <code>type="g"</code> is conceptually different from that of other <code>type</code> values (which are all data-dependent). Using the <code>grid</code> argument also allows more flexibility.</p> <p>Most generally, <code>grid</code> can be a list of arguments to be supplied to <code>panel.grid</code>, which is called with those arguments. Three shortcuts are available:</p> <p>TRUE: roughly equivalent to <code>list(h = -1, v = -1)</code>  "h": roughly equivalent to <code>list(h = -1, v = 0)</code>  "v": roughly equivalent to <code>list(h = 0, v = -1)</code></p> <p>No grid is drawn if <code>grid = FALSE</code>.</p>
<code>abline</code>	A numeric vector or list, specifying arguments arguments for <code>panel.abline</code> , which is called with those arguments. If specified as a (possibly

named) numeric vector, `abline` is coerced to a list. This allows arguments of the form `abline = c(0, 1)`, which adds the diagonal line, or `abline = c(h = 0, v = 0)`, which adds the x- and y-axes to the plot. Use the list form for finer control; e.g., `abline = list(h = 0, v = 0, col = "grey")`.

For more flexibility, use [panel.abline](#) directly.

`jitter.x`, `jitter.y`

logical, whether the data should be jittered before being plotted.

`factor`, `amount`

controls amount of jittering.

`identifier` A character string that is prepended to the names of grobs that are created by this panel function.

## Details

Creates scatterplot of `x` and `y`, with various modifications possible via the `type` argument. `panel.qq` draws a 45 degree line before calling `panel.xyplot`.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. [xyplot](#)) call.

```

F\_2\_llines

*Replacements of traditional graphics functions*

## Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

## Usage

```

lplot.xy(xy, type, pch, lty, col, cex, lwd,
         font, fontfamily, fontface,
         col.line, col.symbol, alpha, fill,

        font, fontfamily, fontface, cex, ..., identifier, name.type)
## Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
      col, alpha, cex, srt = 0,
      lineheight, font, fontfamily, fontface,
      adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ..., identifier, name.type)

lsegments(x0, y0, x1, y1, x2, y2,
          col, alpha, lty, lwd,
          font, fontface, ..., identifier, name.type)
lrect(xleft, ybottom, xright, ytop,
     x = (xleft + xright) / 2,
     y = (ybottom + ytop) / 2,
     width = xright - xleft,
     height = ytop - ybottom,
     col = "transparent",
     border = "black",

```

```

        lty = 1, lwd = 1, alpha = 1,
        just = "center",
        hjust = NULL, vjust = NULL,
        ..., identifier, name.type)
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
        angle = 30, code = 2, length = 0.25, unit = "inches",
        ends = switch(code, "first", "last", "both"),
        type = "open",
        col = add.line$col,
        alpha = add.line$alpha,
        lty = add.line$lty,
        lwd = add.line$lwd,
        fill = NULL, ..., identifier, name.type)
lpolygon(x, y = NULL,
        border = "black", col = "transparent", fill = NULL,
        font, fontface, ..., identifier, name.type)

panel.lines(...)
panel.points(...)
panel.segments(...)
panel.text(...)
panel.rect(...)
panel.arrows(...)
panel.polygon(...)

```

### Arguments

`x, y, x0, y0, x1, y1, x2, y2, xy`  
locations. `x2` and `y2` are available for for S compatibility.

`length, unit` determines extent of arrow head. `length` specifies the length in terms of unit, which can be any valid grid unit as long as it doesn't need a data argument. `unit` defaults to inches, which is the only option in the base version of the function, [arrows](#).

`angle, code, type, labels, srt, adj, pos, offset`  
arguments controlling behaviour. See respective base functions for details. For `larrows` and `panel.larrows`, `type` is either "open" or "closed", indicating the type of arrowhead.

`ends` serves the same function as `code`, using descriptive names rather than integer codes. If specified, this overrides `code`

`col, alpha, lty, lwd, fill, pch, cex, lineheight, font, fontfamily, fontface, co`  
graphical parameters. `fill` applies to points when `pch` is in 21:25 and specifies the fill color, similar to the `bg` argument in the base graphics function [points](#). For devices that support alpha-transparency, a numeric argument `alpha` between 0 and 1 can controls transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0.

`fill, font` and `fontface` are included in `lpolygon` and `lsegments` only to ensure that they are not passed down (as [gpar](#) does not like them).

`origin` for `type="h"` or `type="H"`, the value to which lines drop down.

`xleft, ybottom, xright, ytop`  
see [rect](#)

```
width, height, just, hjust, vjust
      finer control over rectangles, see grid.rect
...
      extra arguments, passed on to lower level functions as appropriate.
identifier
      A character string that is prepended to the name of the grob that is created.
name.type
      A character value indicating whether the name of the grob should have panel
      or strip information added to it. Typically either "panel", "strip",
      "strip.left", or "" (for no extra information).
```

### Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions `panel.*` are essentially identical to the `l*` versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

### Note

There is a new `type="H"` option wherever appropriate, which is similar to `type="h"`, but with horizontal lines.

F\_2\_panel.functions

*Useful Panel Function Components*

---

### Description

These are predefined panel functions available in lattice for use in constructing new panel functions (often on-the-fly).

### Usage

```
panel.abline(a = NULL, b = 0,
             h = NULL, v = NULL,
             reg = NULL, coef = NULL,
             col, col.line, lty, lwd, alpha, type,
             ...,
             reference = FALSE,
             identifier = "abline")
panel.refline(...)

panel.curve(expr, from, to, n = 101,
```

```

        curve.type = "l",
        col, lty, lwd, type,
        ...,
        identifier = "curve")
panel.rug(x = NULL, y = NULL,
        regular = TRUE,
        start = if (regular) 0 else 0.97,
        end = if (regular) 0.03 else 1,
        x.units = rep("npc", 2),
        y.units = rep("npc", 2),
        col, col.line, lty, lwd, alpha,
        ...,
        identifier = "rug")
panel.average(x, y, fun = mean, horizontal = TRUE,
        lwd, lty, col, col.line, type,
        ...,
        identifier = "linejoin")
panel.linejoin(x, y, fun = mean, horizontal = TRUE,
        lwd, lty, col, col.line, type,
        ...,
        identifier = "linejoin")

panel.fill(col, border, ..., identifier = "fill")
panel.grid(h=3, v=3, col, col.line, lty, lwd, x, y, ..., identifier = "grid")
panel.lmline(x, y, ..., identifier = "lmline")
panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
        n = 50, col, col.line, lwd, lty, type,
        ..., identifier = "mathdensity")

```

## Arguments

<code>x, y</code>	Variables defining the contents of the panel. In <code>panel.grid</code> these are optional and are used only to choose an appropriate method of <code>pretty</code> .
<code>a, b</code>	Coefficients of the line to be added by <code>panel.abline</code> . <code>a</code> can be a vector of length 2, representing the coefficients of the line to be added, in which case <code>b</code> should be missing. <code>a</code> can also be an appropriate 'regression' object, i.e., an object which has a <code>coef</code> method that returns a length 2 numeric vector. The corresponding line will be plotted. The <code>reg</code> argument overrides <code>a</code> if specified.
<code>coef</code>	Coefficients of the line to be added as a vector of length 2.
<code>reg</code>	A (linear) regression object, with a <code>coef</code> method that gives the coefficients of the corresponding regression line.
<code>h, v</code>	For <code>panel.abline</code> , these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For <code>panel.grid</code> , these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. <code>h=-1</code> and <code>v=-1</code> are intended to make the grids aligned with the axis labels. This doesn't always work; all that actually happens is that the locations

are chosen using `pretty`, which is also how the label positions are chosen in the most common cases (but not for factor variables, for instance). `h` and `v` can be negative numbers other than `-1`, in which case `-h` and `-v` (as appropriate) is supplied as the `n` argument to `pretty`.

If `x` and/or `y` are specified in `panel.grid`, they will be used to select an appropriate method for `pretty`. This is particularly useful while plotting date-time objects.

<code>reference</code>	A logical flag determining whether the default graphical parameters for <code>panel.abline</code> should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The <code>panel.refline</code> function is a wrapper around <code>panel.abline</code> that calls it with <code>reference = TRUE</code> .
<code>expr</code>	An expression considered as a function of <code>x</code> , or a function, to be plotted as a curve.
<code>n</code>	The number of points to use for drawing the curve.
<code>from, to</code>	optional lower and upper x-limits of curve. If missing, limits of current panel are used
<code>curve.type</code>	Type of curve (“p” for points, etc), passed to <code>llines</code>
<code>regular</code>	A logical flag indicating whether the ‘rug’ is to be drawn on the ‘regular’ side (left / bottom) or not (right / top).
<code>start, end</code>	endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of <code>regular</code> , and cover 3% of the panel width and height.
<code>x.units, y.units</code>	Character vectors, replicated to be of length two. Specifies the (grid) units associated with <code>start</code> and <code>end</code> above. <code>x.units</code> and <code>y.units</code> are for the rug on the x-axis and y-axis respectively (and thus are associated with <code>start</code> and <code>end</code> values on the y and x scales respectively).
<code>col, col.line, lty, lwd, alpha, border</code>	Graphical parameters.
<code>type</code>	Usually ignored by the panel functions documented here; the argument is present only to make sure an explicitly specified <code>type</code> argument (perhaps meant for another function) does not affect the display.
<code>fun</code>	The function that will be applied to the subset of <code>x</code> values (or <code>y</code> if <code>horizontal</code> is <code>FALSE</code> ) determined by the unique values of <code>y</code> ( <code>x</code> ).
<code>horizontal</code>	A logical flag. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the roles of <code>x</code> and <code>y</code> are switched; <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
<code>dmath</code>	A vectorized function that produces density values given a numeric vector named <code>x</code> , e.g., <code>dnorm</code> .
<code>args</code>	A list giving additional arguments to be passed to <code>dmath</code> .
<code>...</code>	Further arguments, typically graphical parameters, passed on to other low-level functions as appropriate. Color can usually be specified by <code>col</code> , <code>col.line</code> , and <code>col.symbol</code> , the last two overriding the first for lines and points respectively.
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

## Details

`panel.abline` adds a line of the form  $y = a + b * x$ , or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. `panel.refline` is similar, but uses the “reference.line” settings for the defaults.

`panel.grid` draws a reference grid.

`panel.curve` adds a curve, similar to what `curve` does with `add = TRUE`. Graphical parameters for the curve are obtained from the “add.line” setting.

`panel.average` treats one of `x` and `y` as a factor (according to the value of `horizontal`), calculates `fun` applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with `panel.xyplot`, and more commonly with `panel.superpose` to produce interaction plots.

`panel.linejoin` is an alias for `panel.average`. It is retained for back-compatibility, and may go away in future.

`panel.mathdensity` plots a (usually theoretical) probability density function. This can be useful in conjunction with `histogram` and `densityplot` to visually assess goodness of fit (note, however, that `qqmath` is more suitable for this).

`panel.rug` adds a *rug* representation of the (marginal) data to the panel, much like `rug`.

`panel.lmline(x, y)` is equivalent to `panel.abline(lm(y ~ x))`.

       list(points = FALSE, lines = TRUE, columns = 2))

## Superposing a fitted normal density on a Histogram

histogram(~ height | voice.part, data = singer, layout = c(2, 4),
         type = "density", border = "transparent", col.line = "grey60",
         xlab = "Height (inches)",
         ylab = "Density Histogram\n with Normal Fit",
         panel = function(x, ...) {
           panel.histogram(x, ...)
           panel.mathdensity(dmath = dnorm,
                            args = list(mean=mean(x), sd=sd(x)), ...)
```

```
} )
```

---

F_2_panel.loess	<i>Panel Function to Add a LOESS Smooth</i>
-----------------	---

---

## Description

A predefined panel function that can be used to add a LOESS smooth based on the provided data.

## Usage

```
panel.loess(x, y, span = 2/3, degree = 1,
            family = c("symmetric", "gaussian"),
            evaluation = 50,
            lwd, lty, col, col.line, type,
            horizontal = FALSE,
            ..., identifier = "loess")
```

## Arguments

<code>x, y</code>	Variables defining the data to be used.
<code>lwd, lty, col, col.line</code>	Graphical parameters for the added line. <code>col.line</code> overrides <code>col</code> .
<code>type</code>	Ignored. The argument is present only to make sure that an explicitly specified <code>type</code> argument (perhaps meant for another function) does not affect the display.
<code>span, degree, family, evaluation</code>	Arguments to <code>loess.smooth</code> , for which <code>panel.loess</code> is essentially a wrapper.
<code>horizontal</code>	A logical flag controlling which variable is to be treated as the predictor (by default <code>x</code> ) and which as the response (by default <code>y</code> ). If <code>TRUE</code> , the plot is ‘transposed’ in the sense that <code>y</code> becomes the predictor and <code>x</code> the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in <code>bwplot</code> ).
<code>...</code>	Extra arguments, passed on to <code>panel.lines</code> .
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

## Value

The object returned by `loess.smooth`.

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

`Lattice`, `loess.smooth`, `prepanel.loess`

---

F\_2\_panel.qqmathline

*Useful panel function with qqmath*

---

## Description

Useful panel function with qqmath. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

## Usage

```
panel.qqmathline(x, y = x,
                 distribution = qnorm,
                 probs = c(0.25, 0.75),
                 qtype = 7,
                 groups = NULL,
                 ...,
                 identifier = "qqmathline")
```

## Arguments

<code>x</code>	The original sample, possibly reduced to a fewer number of quantiles, as determined by the <code>f.value</code> argument to <code>qqmath</code>
<code>y</code>	an alias for <code>x</code> for backwards compatibility
<code>distribution</code>	quantile function for reference theoretical distribution.
<code>probs</code>	numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
<code>qtype</code>	the type of quantile computation used in <a href="#">quantile</a>
<code>groups</code>	optional grouping variable. If non-null, a line will be drawn for each group.
<code>...</code>	other arguments.
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

---

F\_2\_panel.smoothScatter

*Lattice panel function analogous to smoothScatter*

---

## Description

This function allows the user to place `smoothScatter` plots in lattice graphics.

## Usage

```
panel.smoothScatter(x, y = NULL,
                    nbin = 64, cuts = 255,
                    bandwidth,
                    colramp,
                    nrpoints = 100,
                    transformation = function(x) x^0.25,
                    pch = ".",
                    cex = 1, col="black",
                    range.x,
                    ...,
                    raster = FALSE,
                    subscripts,
                    identifier = "smoothScatter")
```

## Arguments

<code>x</code>	Numeric vector containing x-values or n by 2 matrix containing x and y values.
<code>y</code>	Numeric vector containing y-values (optional). The length of <code>x</code> must be the same as that of <code>y</code> .
<code>nbin</code>	Numeric vector of length 1 (for both directions) or 2 (for x and y separately) containing the number of equally spaced grid points for the density estimation.
<code>cuts</code>	number of cuts defining the color gradient
<code>bandwidth</code>	Numeric vector: the smoothing bandwidth. If missing, these functions come up with a more or less useful guess. This parameter then gets passed on to the function <a href="#">bkde2D</a> .
<code>colramp</code>	Function accepting an integer <code>n</code> as an argument and returning <code>n</code> colors.
<code>nrpoints</code>	Numeric vector of length 1 giving number of points to be superimposed on the density image. The first <code>nrpoints</code> points from those areas of lowest regional densities will be plotted. Adding points to the plot allows for the identification of outliers. If all points are to be plotted, choose <code>nrpoints = Inf</code> .
<code>transformation</code>	Function that maps the density scale to the color scale.
<code>pch, cex</code>	graphical parameters for the <code>nrpoints</code> “outlying” points shown in the display
<code>range.x</code>	see <a href="#">bkde2D</a> for details.
<code>col</code>	<a href="#">points</a> color parameter
<code>...</code>	Further arguments that are passed on to <a href="#">panel.levelplot</a> .
<code>raster</code>	logical; if TRUE, <a href="#">panel.levelplot.raster</a> is used, making potentially smaller output files.

subscripts	ignored, but necessary for handling of ...in certain situations. Likely to be removed in future.
identifier	A character string that is prepended to the names of grobs that are created by this panel function.

### Details

This replicates the display part of the `smoothScatter` function by replacing standard graphics calls by grid-compatible ones.

### Value

The function is called for its side effects, namely the production of the appropriate plots on a graphics device.

### Author(s)

Deepayan Sarkar <deepayan.sarkar@r-project.org>

### Examples

```
ddf <- as.data.frame(matrix(rnorm(40000), ncol = 4) + 3 * rnorm(10000))
ddf[, c(2,4)] <- (-ddf[, c(2,4)])
xyplot(V1 ~ V2 + V3, ddf, outer = TRUE,
       panel = panel.smoothScatter, aspect = "iso")
splom(ddf, panel = panel.smoothScatter, nbin = 64, raster = TRUE)
```

---

F\_2\_panel.spline      *Panel Function to Add a Spline Smooth*

---

### Description

A predefined panel function that can be used to add a spline smooth based on the provided data.

### Usage

```
panel.spline(x, y, npoints = 101,
            lwd = plot.line$lwd,
            lty = plot.line$lty,
            col, col.line = plot.line$col,
            type,
            horizontal = FALSE, ...,
            keep.data = FALSE,
            identifier = "spline")
```

**Arguments**

<code>x, y</code>	Variables defining the data to be used.
<code>npoints</code>	The number of equally spaced points within the range of the predictor at which the fitted model is evaluated for plotting.
<code>lwd, lty, col, col.line</code>	Graphical parameters for the added line. <code>col.line</code> overrides <code>col</code> .
<code>type</code>	Ignored. The argument is present only to make sure that an explicitly specified <code>type</code> argument (perhaps meant for another function) does not affect the display.
<code>horizontal</code>	A logical flag controlling which variable is to be treated as the predictor (by default <code>x</code> ) and which as the response (by default <code>y</code> ). If <code>TRUE</code> , the plot is ‘transposed’ in the sense that <code>y</code> becomes the predictor and <code>x</code> the response. (The name ‘horizontal’ may seem an odd choice for this argument, and originates from similar usage in <code>bwplot</code> ).
<code>keep.data</code>	Passed on to <code>smooth.spline</code> . The default here ( <code>FALSE</code> ) is different, and results in the original data not being retained in the fitted spline model. It may be useful to set this to <code>TRUE</code> if the return value of <code>panel.spline</code> , which is the fitted model as returned by <code>smooth.spline</code> , is to be used for subsequent computations.
<code>...</code>	Extra arguments, passed on to <code>smooth.spline</code> and <code>panel.lines</code> as appropriate.
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

**Value**

The fitted model as returned by `smooth.spline`.

---

F\_2\_panel.superpose

*Panel Function for Display Marked by groups*

---

**Description**

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The `x` (and `y` where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

**Usage**

```

panel.superpose(x, y = NULL, subscripts, groups,
               panel.groups = "panel.xyplot",
               ...,
               col, col.line, col.symbol,
               pch, cex, fill, font,
               fontface, fontfamily,
               lty, lwd, alpha,
               type = "p", grid = FALSE,
               distribute.type = FALSE)
panel.superpose.2(..., distribute.type = TRUE)

panel.superpose.plain(...,
                    col, col.line, col.symbol,
                    pch, cex, fill, font,
                    fontface, fontfamily,
                    lty, lwd, alpha)

```

**Arguments**

- |                           |  |
|---------------------------|--|
| <code>x, y</code>         | Coordinates of the points to be displayed. Usually numeric.  |
| <code>panel.groups</code> | <p>The panel function to be used for each subgroup of points. Defaults to <code>panel.xyplot</code>.</p> <p>To be able to distinguish between different levels of the originating group inside <code>panel.groups</code>, it will be supplied two special arguments called <code>group.number</code> and <code>group.value</code> which will hold the numeric code and factor level corresponding to the current level of <code>groups</code>. No special care needs to be taken when writing a <code>panel.groups</code> function if this feature is not used.</p>  |
| <code>subscripts</code>   | An integer vector of subscripts giving indices of the <code>x</code> and <code>y</code> values in the original data source. See the corresponding entry in <a href="#">xyplot</a> for details.   |
| <code>groups</code>       | A grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of <code>groups</code> . The default graphical parameters are obtained from the <code>"superpose.symbol"</code> and <code>"superpose.line"</code> settings using <a href="#">trellis.par.get</a> wherever appropriate.   |
| <code>type</code>         | <p>Usually a character vector specifying how each group should be drawn. Formally, it is passed on to the <code>panel.groups</code> function, which must know what to do with it. By default, <code>panel.groups</code> is <a href="#">panel.xyplot</a>, whose help page describes the admissible values.</p> <p>The functions <code>panel.superpose</code> and <code>panel.superpose.2</code> differ only in the default value of <code>distribute.type</code>, which controls the way the <code>type</code> argument is interpreted. If <code>distribute.type = FALSE</code>, then the interpretation is the same as for <code>panel.xyplot</code> for each of the unique groups. In other words, if <code>type</code> is a vector, all the individual components are honoured concurrently. If <code>distribute.type = TRUE</code>, <code>type</code> is replicated to be as long as the number of unique values in <code>groups</code>, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying <code>type</code> as a list, each component being the desired <code>type</code> vector for the corresponding group.</p> |

	If <code>distribute.type = FALSE</code> , any occurrence of "g" in <code>type</code> causes a grid to be drawn, and all such occurrences are removed before <code>type</code> is passed on to <code>panel.groups</code> .
<code>grid</code>	Logical flag specifying whether a background reference grid should be drawn. See <a href="#">panel.xyplot</a> for details.
<code>col</code>	A vector color specification. See Details.
<code>col.line</code>	A vector color specification. See Details.
<code>col.symbol</code>	A vector color specification. See Details.
<code>pch</code>	A vector plotting character specification. See Details.
<code>cex</code>	A vector size factor specification. See Details.
<code>fill</code>	A vector fill color specification. See Details.
<code>font, fontface, fontfamily</code>	A vector color specification. See Details.
<code>lty</code>	A vector color specification. See Details.
<code>lwd</code>	A vector color specification. See Details.
<code>alpha</code>	A vector alpha-transparency specification. See Details.
<code>...</code>	Extra arguments. Passed down to <code>panel.superpose</code> from <code>panel.superpose.2</code> , and to <code>panel.groups</code> from <code>panel.superpose</code> .
<code>distribute.type</code>	logical controlling interpretation of the <code>type</code> argument.

## Details

`panel.superpose` divides up the  $x$  (and optionally  $y$ ) variable(s) by the unique values of `groups[subscripts]`, and plots each subset with different graphical parameters. The graphical parameters (`col.symbol`, `pch`, etc.) are usually supplied as suitable atomic vectors, but can also be lists. When `panel.groups` is called for the  $i$ -th level of `groups`, the corresponding element of each graphical parameter is passed to it. In the list form, the individual components can themselves be vectors.

The actual plot for each subgroup is created by the `panel.groups` function. With the default `panel.groups`, the `col` argument is overridden by `col.line` and `col.symbol` for lines and points respectively, which default to the "superpose.line" and "superpose.symbol" settings. However, `col` will still be supplied as an argument to `panel.groups` functions that make use of it, with a default of "black". The defaults of other graphical parameters are also taken from the "superpose.line" and "superpose.symbol" settings as appropriate. The `alpha` parameter takes its default from the "superpose.line" setting.

`panel.superpose` and `panel.superpose.2` differ essentially in how `type` is interpreted by default. The default behaviour in `panel.superpose` is the opposite of that in `S`, which is the same as that of `panel.superpose.2`.

`panel.superpose.plain` is the same as `panel.superpose`, except that the default settings for the style arguments are the same for all groups and are taken from the default plot style. It is used in [xyplot.ts](#).

## Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org> (`panel.superpose.2` originally contributed by Neil Klepeis)

Different functions when used as `panel.groups` gives different types of plots, for example [panel.xyplot](#), [panel.dotplot](#) and [panel.average](#) (This can be used to produce interaction plots).

See [Lattice](#) for an overview of the package, and [xyplot](#) for common arguments (in particular, the discussion of the extended formula interface and the `groups` argument).

---

F\_2\_panel.violin      *Panel Function to create Violin Plots*

---

**Description**

This is a panel function that can create a violin plot. It is typically used in a high-level call to `bwplot`.

**Usage**

```
panel.violin(x, y, box.ratio = 1, box.width,
             horizontal = TRUE,
             alpha, border, lty, lwd, col,
             varwidth = FALSE,
             bw, adjust, kernel, window,
             width, n = 50, from, to, cut,
             na.rm, ...,
             identifier = "violin")
```

**Arguments**

<code>x, y</code>	numeric vector or factor. Violin plots are drawn for each unique value of <code>y</code> ( <code>x</code> ) if <code>horizontal</code> is <code>TRUE</code> ( <code>FALSE</code> )
<code>box.ratio</code>	ratio of the thickness of each violin and inter violin space
<code>box.width</code>	thickness of the violins in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. See documentation of <a href="#">bwplot</a> for a fuller explanation.
<code>alpha, border, lty, lwd, col</code>	graphical parameters controlling the violin. Defaults are taken from the “plot.polygon” settings.
<code>varwidth</code>	logical. If <code>FALSE</code> , the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by <code>box.ratio</code> ). If <code>TRUE</code> , densities across violins will have comparable scale.
<code>bw, adjust, kernel, window, width, n, from, to, cut, na.rm</code>	arguments to <a href="#">density</a> , passed on as appropriate
<code>...</code>	arguments passed on to <a href="#">density</a> .
<code>identifier</code>	A character string that is prepended to the names of grobs that are created by this panel function.

**Details**

Creates Violin plot of  $x$  for every level of  $y$ . Note that most arguments controlling the display can be supplied to the high-level (typically `bwplot`) call directly.

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

[bwplot](#), [density](#)

**Examples**

```
bwplot(voice.part ~ height, singer,
       panel = function(..., box.ratio) {
         panel.violin(..., col = "transparent",
                      varwidth = FALSE, box.ratio = box.ratio)
         panel.bwplot(..., fill = NULL, box.ratio = .1)
       } )
```

---

F\_3\_prepanel.default

*Default Prepanel Functions*

---

**Description**

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

**Usage**

```
prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance,
                       xlim, ylim, zlim,
                       screen = list(z = 40, x = -60),
                       R.mat = diag(4),
                       aspect = c(1, 1), panel.aspect = 1,
                       ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
                       groups, subscripts, ..., tails.n = 0)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)
```

**Arguments**

<code>x, y</code>	x and y values, numeric or factor
<code>horizontal</code>	logical, applicable when one of the variables is to be treated as categorical (factor or shingle).
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
<code>nlevels</code>	number of levels of such a categorical variable.
<code>origin, stack</code>	for barcharts or the <code>type="h"</code> plot type
<code>breaks, equal.widths, type, nint</code>	details of histogram calculations. <code>type</code> has a different meaning in <code>prepanel.default.xyplot</code> (see <a href="#">panel.xyplot</a> )
<code>groups, subscripts</code>	See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.
<code>weights</code>	numeric vector of weights for the density calculations. If this is specified, it is subsetted by <code>subscripts</code> to match it to <code>x</code> .
<code>perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zo</code>	see <a href="#">panel.cloud</a>
<code>f.value, distribution, tails.n</code>	see <code>panel.qqmath</code>
<code>darg</code>	list of arguments passed to <a href="#">density</a>
<code>z</code>	see <a href="#">panel.parallel</a> and <a href="#">panel.pairs</a>
<code>qtype</code>	type of <a href="#">quantile</a>
<code>...</code>	other arguments, usually ignored

**Value**

A list with components `xlim`, `ylim`, `dx` and `dy`, and possibly `xat` and `yat`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for [xyplot](#).

**Author(s)**

Deepayan Sarkar <[Deepayan.Sarkar@R-project.org](mailto:Deepayan.Sarkar@R-project.org)>

**See Also**

[xyplot](#), [banking](#), [Lattice](#). See documentation of corresponding panel functions for more details about the arguments.

---

F\_3\_prepanel.functions

*Useful Prepanel Function for Lattice*

---

## Description

These are predefined prepanel functions available in Lattice.

## Usage

```
prepanel.lmline(x, y, ...)
prepanel.qqmathline(x, y = x, distribution = qnorm,
                    probs = c(0.25, 0.75), qtype = 7,
                    groups, subscripts,
                    ...)
prepanel.loess(x, y, span, degree, family, evaluation,
              horizontal = FALSE, ...)
prepanel.spline(x, y, npoints = 101,
               horizontal = FALSE, ...,
               keep.data = FALSE)
```

## Arguments

<code>x, y</code>	<code>x</code> and <code>y</code> values, numeric or factor
<code>distribution</code>	quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in <code>qqmath</code> .
<code>qtype</code>	type of <a href="#">quantile</a>
<code>probs</code>	numeric vector of length two, representing probabilities. If used with <code>aspect="xy"</code> , the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible.
<code>span, degree, family, evaluation</code>	Arguments controlling the underlying <a href="#">loess</a> smooth.
<code>horizontal, npoints</code>	See documentation for corresponding panel function.
<code>keep.data</code>	Ignored. Present to capture argument of the same name in <a href="#">smooth.spline</a> .
<code>groups, subscripts</code>	See <a href="#">xyplot</a> . Whenever appropriate, calculations are done separately for each group and then combined.
<code>...</code>	Other arguments. These are passed on to other functions if appropriate (in particular, <a href="#">smooth.spline</a> ), and ignored otherwise.

## Details

All these prepanel functions compute the limits to be large enough to contain all points as well as the relevant smooth.

In addition, `prepanel.lmline` computes the `dx` and `dy` such that it reflects the slope of the linear regression line; for `prepanel.qqmathline`, this is the slope of the line passing through the quantile pairs specified by `probs`. For `prepanel.loess` and `prepanel.spline`, `dx` and `dy` reflect the piecewise slopes of the nonlinear smooth.

**Value**

usually a list with components `xlim`, `ylim`, `dx` and `dy`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under `xyplot`. There are also several `prepanel` functions that serve as the default for high level functions, see `prepanel.default.xyplot`

**Author(s)**

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

**See Also**

`Lattice`, `xyplot`, `banking`, `panel.loess`, `panel.spline`.

---

G\_axis.default

*Default axis annotation utilities*

---

**Description**

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the `axis` argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

**Usage**

```
xscale.components.default(lim,
                          packet.number = 0,
                          packet.list = NULL,
                          top = TRUE,
                          ...)
yscale.components.default(lim,
                          packet.number = 0,
                          packet.list = NULL,
                          right = TRUE,
                          ...)
axis.default(side = c("top", "bottom", "left", "right"),
             scales, components, as.table,
             labels = c("default", "yes", "no"),
             ticks = c("default", "yes", "no"),
             ..., prefix)
```

**Arguments**

`lim` the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the various date-time representations, they could be vectors of length 2 with the corresponding class.

<code>packet.number</code>	which packet (counted according to the packet order, described in <a href="#">print.trellis</a> ) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.
<code>packet.list</code>	list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)
<code>top, right</code>	the value of the <code>top</code> and <code>right</code> components of the result, as appropriate. See below for interpretation.
<code>side</code>	on which side the axis is to be drawn. The usual partial matching rules apply.
<code>scales</code>	the appropriate component of the <code>scales</code> argument supplied to the high level function, suitably standardized.
<code>components</code>	list, similar to those produced by <code>xscale.components.default</code> and <code>yscale.components.default</code> .
<code>as.table</code>	the <code>as.table</code> argument in the high level function.
<code>labels</code>	whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.
<code>ticks</code>	whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.
<code>...</code>	many other arguments may be supplied, and are passed on to other internal functions.
<code>prefix</code>	A character string identifying the plot being drawn (see <a href="#">print.trellis</a> ). Used to retrieve location of current panel in the overall layout, so that axes can be drawn appropriately.

## Details

These functions are part of a new API introduced in `lattice 0.14` to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

## Value

`xscale.components.default` and `yscale.components.default` return a list of the form suitable as the `components` argument of `axis.default`. Valid components in the return value of `xscale.components.default` are:

<code>num.limit</code>	A numeric limit for the box.
<code>bottom</code>	A list with two elements, <code>ticks</code> and <code>labels</code> . <code>ticks</code> must be a list with components <code>at</code> and <code>tck</code> which give the location and lengths of tick marks. <code>tck</code> can be a vector, and will be recycled to be as long as <code>at</code> . <code>labels</code> must be a list with components <code>at</code> , <code>labels</code> , and <code>check.overlap</code> . <code>at</code> and <code>labels</code> give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. <code>check.overlap</code> is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering.

`top` This can be a logical flag; if `TRUE`, `top` is treated as being the same as `bottom`; if `FALSE`, axis annotation for the top axis is omitted. Alternatively, `top` can be a list like `bottom`.

Valid components in the return value of `yscale.components.default` are `left` and `right`. Their interpretations are analogous to (respectively) the `bottom` and `top` components described above.

---

G\_banking

*Banking*

---

### Description

Calculates banking slope

### Usage

```
banking(dx, dy)
```

### Arguments

`dx`, `dy`            vector of consecutive x, y differences.

## Details

banking is the banking function used when `aspect = "xy"` in high level Trellis functions. It is usually not very meaningful except with `xyplot`. It considers the absolute slopes (based on `dx` and `dy`) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs' website (see [Lattice](#)), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying `lattice.options("banking")`.

## with and without banking

plot <- xyplot(sunspot.year ~ 1700:1988, xlab = "", type = "l",
              scales = list(x = list(alternating = 2)),
              main = "Yearly Sunspots")
print(plot, position = c(0, .3, 1, .9), more = TRUE)
print(update(plot, aspect = "xy", main = "", xlab = "Year"),
      position = c(0, 0, 1, .3))

## cut-and-stack plot (see also xyplot.ts)

xyplot(sunspot.year ~ time(sunspot.year) | equal.count(time(sunspot.year)),
      xlab = "", type = "l", aspect = "xy", strip = FALSE,
      scales = list(x = list(alternating = 2, relation = "sliced")),
      as.table = TRUE, main = "Yearly Sunspots")
```

---

G\_latticeParseFormula

*Parse Trellis formula*

---

## Description

this function is used by high level Lattice functions like `xyplot` to parse the formula argument and evaluate various components of the data.

**Usage**

```
latticeParseFormula(model, data, dimension = 2,
                    subset = TRUE, groups = NULL,
                    multiple, outer,
                    subscripts,
                    drop)
```

**Arguments**

model	the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the <code>dimension</code> argument. The 2d formulas are of the form <code>y ~ x   g1 * ... * gn</code> , and the 3d formulas are of the form <code>z ~ x * y   g1 * ... * gn</code> . In the first form, <code>y</code> may be omitted. The conditioning variables <code>g1, ..., gn</code> can be omitted in either case.
data	the environment/dataset where the variables in the formula are evaluated.
dimension	dimension of the model, see above
subset	index for choosing a subset of the data frame
groups	the grouping variable, if present
multiple, outer	logicals, determining how a '+' in the y and x components of the formula are processed. See <a href="#">xyplot</a> for details
subscripts	logical, whether subscripts are to be calculated
drop	logical or list, similar to the <code>drop.unused.levels</code> argument in <a href="#">xyplot</a> , indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

**Value**

returns a list with several components, including `left`, `right`, `left.name`, `right.name`, `condition` for 2-D, and `left`, `right.x`, `right.y`, `left.name`, `right.x.name`, `right.y.name`, `condition` for 3-D. Other possible components are `groups`, `subscr`

**Author(s)**

[xyplot](#), [Lattice](#)

## Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

## Usage

```
packet.panel.default(layout, condlevels, page, row, column,
                     skip, all.pages.skip = TRUE)
```

## Arguments

layout	the layout argument in high level functions, suitably standardized.
condlevels	a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels
page, row, column	the location of the panel in the coordinate system of pages, rows and columns.
skip	the skip argument in high level functions
all.pages.skip	whether skip should be replicated over all pages. If FALSE, skip will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

## Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is *p*, then the *i*-th conditioning variable will have level `condlevels[[i]][p[i]]`.

## Examples

```
packet.panel.page <- function(n)
{
  ## returns a function that when used as the 'packet.panel'
  ## argument in print.trellis plots page number 'n' only
  function(layout, page, ...) {
    stopifnot(layout[3] == 1)
    packet.panel.default(layout = layout, page = n, ...)
  }
}
```

```

}

data(mtcars)
HP <- equal.count(mtcars$hp, 6)
p <-
  xyplot(mpg ~ disp | HP * factor(cyl),
         mtcars, layout = c(0, 6, 1))

print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))

```

G\_panel.axis

*Panel Function for Drawing Axis Ticks and Labels***Description**

`panel.axis` is the function used by `lattice` to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. `current.panel.limits` can be used to retrieve a panel's x and y limits.

**Usage**

```

panel.axis(side = c("bottom", "left", "top", "right"),
           at,
           labels = TRUE,
           draw.labels = TRUE,
           check.overlap = FALSE,
           outside = FALSE,
           ticks = TRUE,
           half = !outside,
           which.half,
           tck = as.numeric(ticks),
           rot = if (is.logical(labels)) 0 else c(90, 0),
           text.col, text.alpha, text.cex, text.font,
           text.fontfamily, text.fontface, text.lineheight,
           line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")

```

**Arguments**

<code>side</code>	A character string indicating which side axes are to be drawn on. Partial specification is allowed.
<code>at</code>	Numeric vector giving location of labels.
<code>labels</code>	The labels to go along with <code>at</code> . The labels can be a character vector or a vector of expressions. Alternatively, <code>at</code> can be a logical flag: If TRUE, the labels are derived from <code>at</code> , otherwise, labels are empty.
<code>draw.labels</code>	A logical indicating whether labels are to be drawn.

<code>check.overlap</code>	A logical, whether to check for overlapping of labels. This also has the effect of removing at values that are ‘too close’ to the limits.
<code>outside</code>	A logical flag, indicating whether to draw the labels outside the panel or inside. Note that <code>outside=TRUE</code> will only have a visible effect if clipping is disabled for the viewport (panel).
<code>ticks</code>	Logical flag, whether to draw the tickmarks.
<code>half</code>	Logical flag, indicating whether only around half the scales will be drawn for each side. This is primarily used for axis labeling in <a href="#">splom</a> .
<code>which.half</code>	Character string, either "lower" or "upper", indicating which half is to be used for tick locations if <code>half = TRUE</code> . Defaults to whichever is suitable for <a href="#">splom</a> .
<code>tck</code>	A numeric scalar multiplier for tick length. Can be negative, in which case the ticks point inwards.
<code>rot</code>	Rotation angle(s) for labels in degrees. Can be a vector of length 2 for x- and y-axes.
<code>text.col</code>	Color for the axis label text. See <a href="#">gpar</a> for more details on this and the other graphical parameters listed below.
<code>text.alpha</code>	Alpha-transparency value for the axis label text.
<code>text.cex</code>	Size multiplier for the axis label text.
<code>text.font, text.fontfamily, text.fontface</code>	Font for the axis label text.
<code>text.lineheight</code>	Line height for the axis label text.
<code>line.col</code>	Color for the axis label text.
<code>line.lty</code>	Color for the axis.
<code>line.lwd</code>	Color for the axis.
<code>line.alpha</code>	Alpha-transparency value for the axis.
<code>unit</code>	Which grid <a href="#">unit</a> the values should be in.

### Details

`panel.axis` can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in [panel.pairs](#) for [splom](#), as well as for all the usual axis drawing by the `print` method for "trellis" objects. It can also be used to enhance plots ‘after the fact’ by adding axes.

### Value

`current.panel.limits` returns a list with components `xlim` and `ylim`, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by `unit`, by default "native".

### Author(s)

G\_panel.number

*Accessing Auxiliary Information During Plotting***Description**

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the `panel`, `strip` and `axis` functions. Note that this information is not available to the `prepanel` function, which is executed prior to the actual plotting.

**Usage**

```
current.row(prefix)
current.column(prefix)
panel.number(prefix)
packet.number(prefix)
which.packet(prefix)

trellis.currentLayout(which = c("packet", "panel"), prefix)
```

**Arguments**

<code>which</code>	whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).
<code>prefix</code>	A character string acting as a prefix identifying the plot of a "trellis" object. Only relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed. See <a href="#">trellis.focus</a> .

**Value**

`trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

**Note**

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls.

You should also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

G_utilities.3d	Utility functions for 3-D plots
----------------	---------------------------------

---

## Description

These are (related to) the default panel functions for `cloud` and `wireframe`.

## Usage

```
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)
```

## Arguments

<code>x</code>	<code>x</code> can be a numeric matrix with 3 rows for <code>ltransform3dto3d</code>
<code>screen</code>	list, as described in <a href="#">panel.cloud</a>
<code>R.mat</code>	4x4 transformation matrix in homogeneous coordinates
<code>dist</code>	controls transformation to account for perspective viewing

## Details

`ltransform3dMatrix` and `ltransform3dto3d` are utility functions to help in computation of projections. These functions are used inside the panel functions for `cloud` and `wireframe`. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the `screen` argument in `cloud` and `wireframe` and a `R.mat`, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying `R.mat` followed by the rotations in `screen`. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

H\_barley

*Yield data from a Minnesota barley trial***Description**

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

**Usage**

```
barley
```

**Format**

A data frame with 120 observations on the following 4 variables.

**yield** Yield (averaged across three blocks) in bushels/acre.

**variety** Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Trebi".

**year** Factor with levels 1932, 1931

**site** Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

**Details**

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year\*Site\*Variety\*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

H\_ethanol

*Engine exhaust fumes from burning ethanol***Description**

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

**Usage**

```
ethanol
```

**Format**

A data frame with 88 observations on the following 3 variables.

**NOx** Concentration of nitrogen oxides (NO and NO2) in micrograms/J.

**C** Compression ratio of the engine.

**E** Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

**Author(s)**

Documentation contributed by Kevin Wright.

})
```

---

H\_melanoma

---

*Melanoma skin cancer incidence*

---

**Description**

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

**Usage**

```
melanoma
```

**Format**

A data frame with 37 observations on the following 2 variables.

**year** Years 1936 to 1972.

**incidence** Rate of melanoma cancer per 100,000 population.

**Note**

This dataset is not related to the `melanoma` dataset in the `boot` package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per *million*, but this is not consistent with data found at the National Cancer Institute (<http://www.nci.nih.gov>).

**Author(s)**

Documentation contributed by Kevin Wright.

**Examples**

```
# Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
       data = melanoma,
       aspect = "xy",
       panel = function(x, y)
         panel.xyplot(x, y, type="o", pch = 16),
       ylim = c(0, 6),
       xlab = "Year",
       ylab = "Incidence")
```

---

H\_singer

*Heights of New York Choral Society singers*

---

**Description**

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

**Usage**

```
singer
```

**Format**

A data frame with 235 observations on the following 2 variables.

**height** Height in inches of the singers.

**voice.part** (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

**Author(s)**

Documentation contributed by Kevin Wright.

**Source**

**References**

Cleveland, William S. (1993) *Visualizing Data*. Hobart Press, Summit, New Jersey.

**Examples**

```
# Separate histogram for each voice part (Figure 1.2 from Cleveland)
histogram(~ height | voice.part,
          data = singer,
          aspect=1,
          layout = c(2, 4),
          nint=15,
          xlab = "Height (inches)")

# Quantile-Quantile plot (Figure 2.11 from Cleveland)
qqmath(~ height | voice.part,
       data=singer,
       aspect=1,
       layout=c(2,4),
       prepanel = prepanel.qqmathline,
       panel = function(x, ...) {
         panel.grid()
         panel.qqmathline(x, ...)
         panel.qqmath(x, ...)
       },
       xlab = "Unit Normal Quantile",
       ylab="Height (inches)")
```

---

I\_lset

---

Interface to modify Trellis Settings - Defunct

---

**Description**

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

**Usage**

```
lset(theme = col.whitebg())
```

**Arguments**

theme	a list describing how to change the settings of the current active device. Valid components are those in the list returned by <code>trellis.par.get()</code> . Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

## Chapter 24

# The mgcv package

---

`anova.gam`

*Approximate hypothesis tests related to GAM fits*

---

### Description

Performs hypothesis tests relating to one or more fitted `gam` objects. For a single fitted `gam` object, Wald tests of the significance of each parametric and smooth term are performed, so interpretation is analogous to [drop1](#) rather than `anova.lm` (i.e. it's like type III ANOVA, rather than a sequential type I ANOVA). Otherwise the fitted models are compared using an analysis of deviance table: this latter approach should not be use to test the significance of terms which can be penalized to zero. See details.

### Usage

```
## S3 method for class 'gam'
anova(object, ..., dispersion = NULL, test = NULL,
       freq = FALSE, p.type=0)
## S3 method for class 'anova.gam'
print(x, digits = max(3, getOption("digits") - 3), ...)
```

### Arguments

<code>object, ...</code>	fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .
<code>x</code>	an <code>anova.gam</code> object produced by a single model call to <code>anova.gam()</code> .
<code>dispersion</code>	a value for the dispersion parameter: not normally used.
<code>test</code>	what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp".
<code>freq</code>	whether to use frequentist or Bayesian approximations for parametric term p-values. See <a href="#">summary.gam</a> for details.
<code>p.type</code>	selects exact test statistic to use for single smooth term p-values. See <a href="#">summary.gam</a> for details.
<code>digits</code>	number of digits to use when printing output.

## Details

If more than one fitted model is provided than `anova.glm` is used, with the difference in model degrees of freedom being taken as the difference in effective degrees of freedom. The p-values resulting from this are only approximate, and must be used with care. The approximation is most accurate when the comparison relates to unpenalized terms, or smoothers with a null space of dimension greater than zero. (Basically we require that the difference terms could be well approximated by unpenalized terms with degrees of freedom approximately the effective degrees of freedom). In simulations the p-values are usually slightly too low. For terms with a zero-dimensional null space (i.e. those which can be penalized to zero) the approximation is often very poor, and significance can be greatly overstated: i.e. p-values are often substantially too low. This case applies to random effect terms.

Note also that in the multi-model call to `anova.gam`, it is quite possible for a model with more terms to end up with lower effective degrees of freedom, but better fit, than the notionally null model with fewer terms. In such cases it is very rare that it makes sense to perform any sort of test, since there is then no basis on which to accept the notional null model.

If only one model is provided then the significance of each model term is assessed using Wald like tests, conditional on the smoothing parameter estimates: see `summary.gam` and Wood (2013a,b) for details. The p-values provided here are better justified than in the multi model case, and have close to the correct distribution under the null, unless smoothing parameters are poorly identified. ML or REML smoothing parameter selection leads to the best results in simulations as they tend to avoid occasional severe undersmoothing. In replication of the full simulation study of Scheipl et al. (2008) the tests give almost indistinguishable power to the method recommended there, but slightly too low p-values under the null in their section 3.1.8 test for a smooth interaction (the Scheipl et al. recommendation is not used directly, because it only applies in the Gaussian case, and requires model refits, but it is available in package `RLRsim`).

In the single model case `print.anova.gam` is used as the printing method.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good.

## Value

In the multi-model case `anova.gam` produces output identical to `anova.glm`, which it in fact uses.

In the single model case an object of class `anova.gam` is produced, which is in fact an object returned from `summary.gam`.

`print.anova.gam` simply produces tabulated output.

## WARNING

If models 'a' and 'b' differ only in terms with no un-penalized components then p values from `anova(a,b)` are unreliable, and usually much too low.

Default P-values will usually be wrong for parametric terms penalized using 'paraPen': use `freq=TRUE` to obtain better p-values when the penalties are full rank and represent conventional random effects.

For a single model, interpretation is similar to `drop1`, not `anova.lm`.

[gam](#), [predict.gam](#), [gam.check](#), [summary.gam](#)

**Examples**

```
library(mgcv)
set.seed(0)
dat <- gamSim(5,n=200,scale=2)

b<-gam(y ~ x0 + s(x1) + s(x2) + s(x3),data=dat)
anova(b)
b1<-gam(y ~ x0 + s(x1) + s(x2),data=dat)
anova(b,b1,test="F")
```

**Description**

Fits a generalized additive model (GAM) to a very large data set, the term ‘GAM’ being taken to include any quadratically penalized GLM. The degree of smoothness of model terms is estimated as part of fitting. In use the function is much like [gam](#), except that the numerical methods are designed for datasets containing upwards of several tens of thousands of data (see Wood, Goude and Shaw, 2015). The advantage of `bam` is much lower memory footprint than [gam](#), but it can also be much faster, for large datasets. `bam` can also compute on a cluster set up by the [parallel](#) package.

An alternative fitting approach is provided by the `discrete==TRUE` method. In this case a method based on discretization of covariate values and C code level parallelization (controlled by the `nthreads` argument instead of the `cluster` argument) is used. This extends both the data set and model size usable.

## Usage

```
bam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
    na.action=na.omit, offset=NULL, method="fREML", control=list(),
    scale=0, gamma=1, knots=NULL, sp=NULL, min.sp=NULL, paraPen=NULL,
    chunk.size=10000, rho=0, AR.start=NULL, discrete=FALSE, sparse=FALSE,
    cluster=NULL, nthreads=NA, gc.level=1, use.chol=FALSE, samfrac=1,
    drop.unused.levels=TRUE, G=NULL, fit=TRUE, ...)
```

## Arguments

formula	A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> and <code>te</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).
family	This is a family object specifying the distribution and link to use in fitting etc. See <a href="#">glm</a> and <a href="#">family</a> for more details. A negative binomial family is provided: see <a href="#">negbin</a> , but only the known theta case is supported by <code>bam</code> .
data	A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.
weights	prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. <code>weights &lt;- weights/mean(weights)</code> ).
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
offset	Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula: this conforms to the behaviour of <code>lm</code> and <code>glm</code> .
method	The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Default "fREML" uses fast REML computation.
control	A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values.
scale	If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.
gamma	It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE/AIC score by a constant multiplier. This allows such a multiplier to be supplied.

knots	this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the " <code>tp</code> " / " <code>ts</code> " case. Different terms can use different numbers of knots, unless they share a covariate.
sp	A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.
min.sp	Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).
paraPen	optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.
chunk.size	The model matrix is created in chunks of this size, rather than ever being formed whole. Reset to <code>4*p</code> if <code>chunk.size &lt; 4*p</code> where <code>p</code> is the number of coefficients.
rho	An AR1 error model can be used for the residuals (based on dataframe order), of Gaussian-identity link models. This is the AR1 correlation parameter. Standardized residuals (approximately uncorrelated under correct model) returned in <code>std.rsd</code> if non zero.
AR.start	logical variable of same length as data, TRUE at first observation of an independent section of AR1 correlation. Very first observation in data frame does not need this. If NULL then there are no breaks in AR1 correlation.
discrete	with <code>method="fREML"</code> it is possible to discretize covariates for storage and efficiency reasons. If <code>discrete</code> is TRUE, a number or a vector of numbers for each smoother term, then discretization happens. If numbers are supplied they give the number of discretization bins. Experimental at present.
sparse	Deprecated. If all smooths are P-splines and all tensor products are of the form <code>te(..., bs="ps", np=FALSE)</code> then in principle computation could be made faster using sparse matrix methods, and you could set this to TRUE. In practice the speed up is disappointing, and the computation is less well conditioned than the default. See details.
cluster	<code>bam</code> can compute the computationally dominant QR decomposition in parallel using <a href="#">parLapply</a> from the <code>parallel</code> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code.
nthreads	Number of threads to use for non-cluster computation (e.g. combining results from cluster nodes). if NA set to <code>max(1, length(cluster))</code> .
gc.level	to keep the memory footprint down, it helps to call the garbage collector often, but this takes a substantial amount of time. Setting this to zero means that garbage collection only happens when R decides it should. Setting to 2 gives frequent garbage collection. 1 is in between.

<code>use.chol</code>	By default <code>bam</code> uses a very stable QR update approach to obtaining the QR decomposition of the model matrix. For well conditioned models an alternative accumulates the crossproduct of the model matrix and then finds its Choleski decomposition, at the end. This is somewhat more efficient, computationally.
<code>samfrac</code>	For very large sample size Generalized additive models the number of iterations needed for the model fit can be reduced by first fitting a model to a random sample of the data, and using the results to supply starting values. This initial fit is run with sloppy convergence tolerances, so is typically very low cost. <code>samfrac</code> is the sampling fraction to use. 0.1 is often reasonable.
<code>drop.unused.levels</code>	by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.
<code>G</code>	if not <code>NULL</code> then this should be the object returned by a previous call to <code>bam</code> with <code>fit=FALSE</code> . Causes all other arguments to be ignored except <code>chunk.size</code> , <code>gamma</code> , <code>nthreads</code> , <code>cluster</code> , <code>rho</code> , <code>gc.level</code> , <code>samfrac</code> , <code>use.chol</code> and <code>method</code> .
<code>fit</code>	if <code>FALSE</code> then the model is set up for fitting but not estimated, and an object is returned, suitable for passing as the <code>G</code> argument to <code>bam</code> .
<code>...</code>	further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).

## Details

`bam` operates by first setting up the basis characteristics for the smooths, using a representative subsample of the data. Then the model matrix is constructed in blocks using `predict.gam`. For each block the factor  $R$ , from the QR decomposition of the whole model matrix is updated, along with  $Q'y$  and the sum of squares of  $y$ . At the end of block processing, fitting takes place, without the need to ever form the whole model matrix.

In the generalized case, the same trick is used with the weighted model matrix and weighted pseudodata, at each step of the PIRLS. Smoothness selection is performed on the working model at each stage (performance oriented iteration), to maintain the small memory footprint. This is trivial to justify in the case of GCV or Cp/UBRE/AIC based model selection, and for REML/ML is justified via the asymptotic multivariate normality of  $Q'z$  where  $z$  is the IRLS pseudodata.

For full method details see Wood, Goude and Shaw (2015).

Note that POI is not as stable as the default nested iteration used with `gam`, but that for very large, information rich, datasets, this is unlikely to matter much.

Note also that it is possible to spend most of the computational time on basis evaluation, if an expensive basis is used. In practice this means that the default "tp" basis should be avoided: almost any other basis (e.g. "cr" or "ps") can be used in the 1D case, and tensor product smooths (te) are typically much less costly in the multi-dimensional case.

If `cluster` is provided as a cluster set up using `makeCluster` (or `makeForkCluster`) from the `parallel` package, then the rate limiting QR decomposition of the model matrix is performed in parallel using this cluster. Note that the speed ups are often not that great. On a multi-core machine it is usually best to set the cluster size to the number of physical cores, which is often less than what is reported by `detectCores`. Using more than the number of physical cores can result in no speed up at all (or even a slow down). Note that a highly parallel BLAS may negate all advantage from using a cluster of cores. Computing in parallel of course requires more memory than computing in series. See examples.

If the deprecated argument `sparse=TRUE` then QR updating is replaced by an alternative scheme, in which the model matrix is stored whole as a sparse matrix. This only makes sense if all smooths

are P-splines and all tensor products are of the form `te(..., bs="ps", np=FALSE)`, but no check is made. The computations are then based on the Choleski decomposition of the crossproduct of the sparse model matrix. Although this crossproduct is nearly dense, sparsity should make its formation efficient, which is useful as it is the leading order term in the operations count. However there is no benefit in using sparse methods to form the Choleski decomposition, given that the crossproduct is dense. In practice the sparse matrix handling overheads mean that modest or no speed ups are produced by this approach, while the computation is less stable than the default, and the memory footprint often higher (but please let the author know if you find an example where the speedup is really worthwhile).

### Value

An object of class "gam" as described in [gamObject](#).

### WARNINGS

The routine will be slow if the default "tp" basis is used.

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

This routine is less stable than 'gam' for the same dataset.

The negbin family is only supported for the \*known theta\* case.

AIC computation does not currently take account of an AR1 model, if used.

```
library(mgcv)
## See help("mgcv-parallel") for using bam in parallel

## Some examples are marked 'Not run' purely to keep
## checking load on CRAN down. Sample sizes are small for
## the same reason.

set.seed(3)
dat <- gamSim(1, n=25000, dist="normal", scale=20)
bs <- "cr"; k <- 12
b <- bam(y ~ s(x0, bs=bs) + s(x1, bs=bs) + s(x2, bs=bs, k=k) +
```

```

      s(x3,bs=bs),data=dat)
summary(b)
plot(b,pages=1,rug=FALSE) ## plot smooths, but not rug
plot(b,pages=1,rug=FALSE,seWithMean=TRUE) ## `with intercept' CIs

## Not run:
ba <- bam(y ~ s(x0,bs=bs,k=k)+s(x1,bs=bs,k=k)+s(x2,bs=bs,k=k)+
          s(x3,bs=bs,k=k),data=dat,method="GCV.Cp") ## use GCV
summary(ba)
## End(Not run)

## A Poisson example...

k <- 15
dat <- gamSim(1,n=21000,dist="poisson",scale=.1)

system.time(b1 <- bam(y ~ s(x0,bs=bs)+s(x1,bs=bs)+s(x2,bs=bs,k=k),
                     data=dat,family=poisson()))
b1

## Sparse smoother example (deprecated)...
## Not run:
dat <- gamSim(1,n=10000,dist="poisson",scale=.1)
system.time( b3 <- bam(y ~ te(x0,x1,bs="ps",k=10,np=FALSE)+
                     s(x2,bs="ps",k=30)+s(x3,bs="ps",k=30),data=dat,
                     method="REML",family=poisson(),sparse=TRUE))
b3
## End(Not run)

```

bam.update

*Update a strictly additive bam model for new data.*

## Description

Gaussian with identity link models fitted by `bam` can be efficiently updated as new data becomes available, by simply updating the QR decomposition on which estimation is based, and re-optimizing the smoothing parameters, starting from the previous estimates. This routine implements this.

## Usage

```
bam.update(b,data,chunk.size=10000)
```

## Arguments

<code>b</code>	A gam object fitted by <code>bam</code> and representing a strictly additive model (i.e. gaussian errors, identity link).
<code>data</code>	Extra data to augment the original data used to obtain <code>b</code> . Must include a <code>weights</code> column if the original fit was weighted and a <code>AR.start</code> column if <code>AR.start</code> was non NULL in original fit.
<code>chunk.size</code>	size of subsets of data to process in one go when getting fitted values.

## Details

`bam.update` updates the QR decomposition of the (weighted) model matrix of the GAM represented by `b` to take account of the new data. The orthogonal factor multiplied by the response vector is also updated. Given these updates the model and smoothing parameters can be re-estimated, as if the whole dataset (original and the new data) had been fitted in one go. The function will use the same AR1 model for the residuals as that employed in the original model fit (see `rho` parameter of `bam`).

Note that there may be small numerical differences in fit between fitting the data all at once, and fitting in stages by updating, if the smoothing bases used have any of their details set with reference to the data (e.g. default knot locations).

## Value

An object of class "gam" as described in `gamObject`.

betar

*GAM beta regression family*

### Description

Family for use with [gam](#), implementing regression for beta distributed data on (0,1). A linear predictor controls the mean,  $\mu$  of the beta distribution, while the variance is then  $\mu(1-\mu)/(1+\phi)$ , with parameter  $\phi$  being estimated during fitting, alongside the smoothing parameters.

### Usage

```
betar(theta = NULL, link = "logit", eps=.Machine$double.eps*100)
```

### Arguments

theta	the extra parameter ( $\phi$ above).
link	The link function: one of "logit", "probit", "cloglog" and "cauchit".
eps	the response variable will be truncated to the interval $[\text{eps}, 1-\text{eps}]$ if there are values outside this range. This truncation is not entirely benign, but too small a value of <code>eps</code> will cause stability problems if there are zeroes or ones in the response.

### Details

These models are useful for proportions data which can not be modelled as binomial. Note the assumption that data are in (0,1), despite the fact that for some parameter values 0 and 1 are perfectly legitimate observations. The restriction is needed to keep the log likelihood bounded for all parameter values. Any data exactly at 0 or 1 are reset to be just above 0 or just below 1 using the `eps` argument (in fact any observation  $< \text{eps}$  is reset to `eps` and any observation  $> 1-\text{eps}$  is reset to  $1-\text{eps}$ ). Note the effect of this resetting. If  $\mu\phi > 1$  then impossible 0s are replaced with highly improbable `eps` values. If the inequality is reversed then 0s with infinite probability density are replaced with `eps` values having high finite probability density. The equivalent condition for 1s is  $(1-\mu)\phi > 1$ . Clearly all types of resetting are somewhat unsatisfactory, and care is needed if data contain 0s or 1s (often it makes sense to manually reset the 0s and 1s in a manner that somehow reflects the sampling setup).

**Value**

An object of class `extended.family`.

**WARNINGS**

Do read the details section if your data contain 0s and or 1s.

a <- mu*phi; b <- phi - a;
dat$y <- rbeta(n,a,b)

bm <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=betar(link="logit"), data=dat)

bm
plot(bm, pages=1)
```

---

choose.k

*Basis dimension choice for smooths*

---

**Description**

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size,  $k$ . When setting up models in the `mgcv` package, using `s` or `te` terms in a model formula,  $k$  must be chosen: the defaults are essentially arbitrary.

In practice  $k-1$  (or  $k$ ) sets the upper limit on the degrees of freedom associated with an `s` smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For `te` smooths the upper limit of the degrees of freedom is given by the product of the  $k$  values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC, REML or whatever is specified. The exception to this is if a smooth is specified using the `fx=TRUE` option, in which case it is unpenalized.

So, exact choice of  $k$  is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of  $k$  informally. If the effective degrees of freedom for a model term are estimated to be much less than  $k-1$  then this is unlikely to be very worthwhile, but as the EDF approach  $k-1$ , checking can be important. A useful

general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased  $k$  to see if there is pattern in the residuals that could potentially be explained by increasing  $k$ . Examples are provided below.

The obvious, but more costly, alternative is simply to increase the suspect  $k$  and refit the original model. If there are no statistically important changes as a result of doing this, then  $k$  was large enough. (Change in the smoothness selection criterion, and/or the effective degrees of freedom, when  $k$  is increased, provide the obvious numerical measures for whether the fit has changed substantially.)

`gam.check` runs a simple simulation based check on the basis dimensions, which can help to flag up terms for which  $k$  is too low. Grossly too small  $k$  will also be visible from partial residuals available with `plot.gam`.

One scenario that can cause confusion is this: a model is fitted with  $k=10$  for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with  $k=20$  and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with  $k=20$  contains a larger subspace of functions with EDF 8.7 than did the function space with  $k=10$ : one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

b
## edf for 3rd smooth is highest as proportion of k -- increase k
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=12)+s(x3,k=6),
        data=dat,method="REML")
b
## edf substantially up, -ve REML substantially down
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=24)+s(x3,k=6),
        data=dat,method="REML")
b
## slight edf increase and -ve REML change

```

```
b <- gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=40)+s(x3,k=6),
        data=dat,method="REML")
b
## definitely stabilized (but really k around 20 would have been fine)
```

columb

*Reduced version of Columbus OH crime data*

## Description

By district crime data from Columbus OH, together with polygons describing district shape. Useful for illustrating use of simple Markov Random Field smoothers.

## Usage

```
data(columb)
data(columb.polys)
```

## Format

`columb` is a 49 row data frame with the following columns

**area** land area of district

**home.value** housing value in 1000USD.

**income** household income in 1000USD.

**crime** residential burglaries and auto thefts per 1000 households.

**open.space** measure of open space in district.

**district** code identifying district, and matching names (`columb.polys`).

`columb.polys` contains the polygons defining the areas in the format described below.

## Details

The data frame `columb` relates to the districts whose boundaries are coded in `columb.polys`. `columb.polys[[i]]` is a 2 column matrix, containing the vertices of the polygons defining the boundary of the *i*th district. `columb.polys[[2]]` has an artificial hole inserted to illustrate how holes in districts can be specified. Different polygons defining the boundary of a district are separated by NA rows in `columb.polys[[1]]`, and a polygon enclosed within another is treated as a hole in that region (a hole should never come first). `names(columb.polys)` matches `columb$district` (order unimportant).

## Source

The data are adapted from the `columbus` example in the `spdep` package, where the original source is given as:

Anselin, Luc. 1988. Spatial econometrics: methods and models. Dordrecht: Kluwer Academic, Table 12.1 p. 189.

## Examples

```

concurvity

*GAM concurvity measures***Description**

Produces summary measures of concurvity between [gam](#) components.

**Usage**

```
concurvity(b, full=TRUE)
```

**Arguments**

<code>b</code>	An object inheriting from class "gam".
<code>full</code>	If <code>TRUE</code> then concurvity of each term with the whole of the rest of the model is considered. If <code>FALSE</code> then pairwise concurvity measures between each smooth term (as well as the parametric component) are considered.

**Details**

Concurvity occurs when some smooth term in a model could be approximated by one or more of the other smooth terms in the model. This is often the case when a smooth of space is included in a model, along with smooths of other covariates that also vary more or less smoothly in space. Similarly it tends to be an issue in models including a smooth of time, along with smooths of other time varying covariates.

Concurvity can be viewed as a generalization of co-linearity, and causes similar problems of interpretation. It can also make estimates somewhat unstable (so that they become sensitive to apparently innocuous modelling details, for example).

This routine computes three related indices of concurvity, all bounded between 0 and 1, with 0 indicating no problem, and 1 indicating total lack of identifiability. The three indices are all based on the idea that a smooth term,  $f$ , in the model can be decomposed into a part,  $g$ , that lies entirely in the space of one or more other terms in the model, and a remainder part that is completely within the term's own space. If  $g$  makes up a large part of  $f$  then there is a concurvity problem. The indices used are all based on the square of  $\|g\|/\|f\|$ , that is the ratio of the squared Euclidean norms of the vectors of  $f$  and  $g$  evaluated at the observed covariate values.

The three measures are as follows

**worst** This is the largest value that the square of  $\|g\|/\|f\|$  could take for any coefficient vector. This is a fairly pessimistic measure, as it looks at the worst case irrespective of data. This is the only measure that is symmetric.

**observed** This just returns the value of the square of  $\|g\|/\|f\|$  according to the estimated coefficients. This could be a bit over-optimistic about the potential for a problem in some cases.

**estimate** This is the squared F-norm of the basis for  $g$  divided by the F-norm of the basis for  $f$ . It is a measure of the extent to which the  $f$  basis can be explained by the  $g$  basis. It does not suffer from the pessimism or potential for over-optimism of the previous two measures, but is less easy to understand.

**Value**

If `full=TRUE` a matrix with one column for each term and one row for each of the 3 concurvity measures detailed below. If `full=FALSE` a list of 3 matrices, one for each of the three concurvity measures detailed below. Each row of the matrix relates to how the model terms depend on the model term supplying that rows name.

## simulate response dependent on t and x...
y <- sin(4*pi*t) + exp(x/20) + rnorm(n)*.3

## fit model...
b <- gam(y ~ s(t,k=15) + s(x,k=15),method="REML")

## assess concurvity between each term and `rest of model'...
concurvity(b)

## ... and now look at pairwise concurvity between terms...
concurvity(b,full=FALSE)
```

---

cox.ph

*Additive Cox Proportional Hazard Model*

---

**Description**

The `cox.ph` family implements the Cox Proportional Hazards model with Peto's correction for ties, and estimation by penalized partial likelihood maximization, for use with `gam`. In the model formula, event time is the response. The `weights` vector provides the censoring information (0 for censoring, 1 for event).

**Usage**

```
cox.ph(link="identity")
```

## Arguments

`link` currently (and possibly for ever) only "identity" supported.

## Details

Used with `gam` to fit Cox Proportional Hazards models to survival data. The model formula will have event/censoring times on the left hand side and the linear predictor specification on the right hand side. Censoring information is provided by the `weights` argument to `gam`, with 1 indicating an event and 0 indicating censoring.

Prediction from the fitted model object (using the `predict` method) with `type="response"` will predict on the survivor function scale. See example code below for extracting the baseline hazard/survival directly. Martingale or deviance residuals can be extracted. The `fitted.values` stored in the model object are survival function estimates for each subject at their event/censoring time.

Estimation of model coefficients is by maximising the log-partial likelihood penalized by the smoothing penalties. See e.g. Hastie and Tibshirani, 1990, section 8.3. for the partial likelihood used (with Peto's approximation for ties), but note that optimization of the partial likelihood does not follow Hastie and Tibshirani. See Klein and Moeschberger (2003) for estimation of residuals, the baseline hazard, survival function and associated standard errors.

The percentage deviance explained reported for Cox PH models is based on the sum of squares of the deviance residuals, as the model deviance, and the sum of squares of the deviance residuals when the covariate effects are set to zero, as the null deviance. The same baseline hazard estimate is used for both.

## Value

An object inheriting from class `general.family`.

## References

cSplineDes

---

*Evaluate cyclic B spline basis*

---

## Description

Uses splineDesign to set up the model matrix for a cyclic B-spline basis.

## Usage

```
cSplineDes(x, knots, ord = 4)
```

**Arguments**

<code>x</code>	covariate values for smooth.
<code>knots</code>	The knot locations: the range of these must include all the data.
<code>ord</code>	order of the basis. 4 is a cubic spline basis. Must be $>1$ .

**Details**

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

**Value**

A matrix with `length(x)` rows and `length(knots)-1` columns.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**See Also**

[cyclic.p.spline](#)

**Examples**

```
require(mgcv)
## create some x's and knots...
n <- 200

  stop("cyclic spline ends don't match!")
```

---

exclude.too.far	<i>Exclude prediction grid points too far from data</i>
-----------------	---

---

### Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements `TRUE` if the corresponding node is too far from data and `FALSE` otherwise. Basically a service routine for `vis.gam` and `plot.gam`.

### Usage

```
exclude.too.far(g1, g2, d1, d2, dist)
```

### Arguments

<code>g1</code>	co-ordinates of grid relative to first axis.
<code>g2</code>	co-ordinates of grid relative to second axis.
<code>d1</code>	co-ordinates of data relative to first axis.
<code>d2</code>	co-ordinates of data relative to second axis.
<code>dist</code>	how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and <code>dist</code> is a distance within this unit square.

### Details

Linear scalings of the axes are first determined so that the grid defined by the nodes in `g1` and `g2` lies exactly in the unit square (i.e. on  $[0,1]$  by  $[0,1]$ ). These scalings are applied to `g1`, `g2`, `d1` and `d2`. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than `dist` the corresponding entry in the returned array is set to `TRUE` (otherwise to `FALSE`). The distance calculations are performed in compiled code for speed without storage overheads.

### Value

A logical array with `TRUE` indicating a node in the grid defined by `g1`, `g2` that is ‘too far’ from any datum.

x<-rnorm(100);y<-rnorm(100) # some "data"
n<-40 # generate a grid...
mx<-seq(min(x),max(x),length=n)
my<-seq(min(y),max(y),length=n)
gx<-rep(mx,n);gy<-rep(my,rep(n,n))
tf<-exclude.too.far(gx,gy,x,y,0.1)
plot(gx[!tf],gy[!tf],pch=".");points(x,y,col=2)
```

---

extract.lme.cov	<i>Extract the data covariance matrix from an lme object</i>
-----------------	--

---

## Description

This is a service routine for [gamm](#). Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation. `extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

## Usage

```
extract.lme.cov(b,data,start.level=1)
extract.lme.cov2(b,data,start.level=1)
```

## Arguments

<code>b</code>	A fitted model object returned by a call to <a href="#">lme</a> .
<code>data</code>	The data frame/ model frame that was supplied to <a href="#">lme</a> .
<code>start.level</code>	The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations.

## Details

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extract that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The `extract.lme.cov` calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. `extract.lme.cov2` is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

[gamm](#) uses `extract.lme.cov2`.

`extract.lme.cov` does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. `extract.lme.cov2` does deal with this situation.

**Value**

For `extract.lme.cov` an estimated covariance matrix.

For `extract.lme.cov2` a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

family.mgcv

*Distribution families in mgcv*

---

**Description**

As well as the standard families documented in [family](#) (see also [glm](#)) which can be used with functions [gam](#), [bam](#) and [gamm](#), `mgcv` also supplies some extra families, most of which are currently only usable with [gam](#). These are described here.

## Details

The following families are in the exponential family given the value of a single parameter. They are usable with all modelling functions.

- [Tweedie](#) An exponential family distribution for which the variance of the response is given by the mean response to the power  $p$ .  $p$  is in (1,2) and must be supplied. See [tw](#) to estimate  $p$ .
- [negbin](#) The negative binomial. See [nb](#) to estimate the `theta` parameter of the negative binomial.

The following families are for regression type models dependent on a single linear predictor, and with a log likelihood which is a sum of independent terms, each corresponding to a single response observation. Usable only with [gam](#), with smoothing parameter estimation by "REML" or "ML" (the latter does not integrate the unpenalized and parameteric effects out of the marginal likelihood optimized for the smoothing parameters).

- [ocat](#) for ordered categorical data.
- [tw](#) for Tweedie distributed data, when the power parameter relating the variance to the mean is to be estimated.
- [nb](#) for negative binomial data when the `theta` parameter is to be estimated.
- [betar](#) for proportions data on (0,1) when the binomial is not appropriate.
- [scat](#) scaled t for heavy tailed data that would otherwise be modelled as Gaussian.
- [zip](#) for zero inflated Poisson data, when the zero inflation rate depends simply on the Poisson mean.

The following families implement more general model classes. Usable only with [gam](#) and only with REML smoothing parameter estimation.

- [cox.ph](#) the Cox Proportional Hazards model for survival data.
- [gaulss](#) a Gaussian location-scale model where the mean and the standard deviation are both modelled using smooth linear predictors.
- [zipplss](#) a 'two-stage' zero inflated Poisson model, in which 'potential-presence' is modelled with one linear predictor, and Poisson mean abundance given potential presence is modelled with a second linear predictor.
- [mvn](#) multivariate normal additive models.

## Description

Generalized Additive Model fitting by 'outer' iteration, requires extra derivatives of the variance and link functions to be added to family objects. The first 3 functions add what is needed. Model checking can be aided by adding quantile and random deviate generating functions to the family. The final two functions do this.

**Usage**

```
fix.family.link(fam)
fix.family.var(fam)
fix.family.ls(fam)
fix.family.qf(fam)
fix.family.rd(fam)
```

**Arguments**

fam                      A family.

**Details**

Consider the first 3 function first.

Outer iteration GAM estimation requires derivatives of the GCV, UBRE/gAIC, GACV, REML or ML score, which are obtained by finding the derivatives of the model coefficients w.r.t. the log smoothing parameters, using the implicit function theorem. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean (and the 4th derivatives if Fisher scoring is not used). Also required are the first and second derivatives of the variance function w.r.t. the mean (plus the third derivative if Fisher scoring is not used). Finally REML or ML estimation of smoothing parameters requires the log saturated likelihood and its first two derivatives w.r.t. the scale parameter. These functions add functions evaluating these quantities to a family.

If the family already has functions `dvar`, `d2var`, `d3var`, `d2link`, `d3link`, `d4link` and for RE/ML `ls`, then these functions simply return the family unmodified: this allows non-standard links to be used with `gam` when using outer iteration (performance iteration operates with unmodified families). Note that if you only need Fisher scoring then `d4link` and `d3var` can be dummy, as they are ignored. similarly `ls` is only needed for RE/ML.

The `dvar` function is a function of a mean vector, `mu`, and returns a vector of corresponding first derivatives of the family variance function. The `d2link` function is also a function of a vector of mean values, `mu`: it returns a vector of second derivatives of the link, evaluated at `mu`. Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a `dvar` and `d2var`, function if your family only requires links that occur in one of the standard families.

The second two functions are useful for investigating the distribution of residuals and are used by `qq.gam`. If possible the functions add quantile (`qf`) or random deviate (`rd`) generating functions to the family. If a family already has `qf` or `rd` functions then it is left unmodified. `qf` functions are only available for some families, and for quasi families neither type of function is available.

**Value**

A family object with extra component functions `dvar`, `d2var`, `d2link`, `d3link`, `d4link`, `ls`, and possibly `qf` and `rd`, depending on which functions are called.

fixDependence*Detect linear dependencies of one matrix on another*

---

**Description**

Identifies columns of a matrix `X2` which are linearly dependent on columns of a matrix `X1`. Primarily of use in setting up identifiability constraints for nested GAMs.

**Usage**

```
fixDependence(X1, X2, tol=.Machine$double.eps^.5, rank.def=0, strict=FALSE)
```

**Arguments**

<code>X1</code>	A matrix.
<code>X2</code>	A matrix, the columns of which may be partially linearly dependent on the columns of <code>X1</code> .
<code>tol</code>	The tolerance to use when assessing linear dependence.
<code>rank.def</code>	If the degree of rank deficiency in <code>X2</code> , given <code>X1</code> , is known, then it can be supplied here, and <code>tol</code> is then ignored. Unused unless positive and not greater than the number of columns in <code>X2</code> .
<code>strict</code>	if <code>TRUE</code> then only columns individually dependent on <code>X1</code> are detected, if <code>FALSE</code> then enough columns to make the reduced <code>X2</code> full rank and independent of <code>X1</code> are detected.

**Details**

The algorithm uses a simple approach based on QR decomposition: see Wood (2006, section 4.10.2) for details.

**Value**

A vector of the columns of `X2` which are linearly dependent on columns of `X1` (or which need to be deleted to achieve independence and full rank if `strict==FALSE`). `NULL` if the two matrices are independent.

**Author(s)**

## Examples

```
library(mgcv)
n<-20;c1<-4;c2<-7
X1<-matrix(runif(n*c1),n,c1)
X2<-matrix(runif(n*c2),n,c2)
X2[,3]<-X1[,2]+X2[,4]*.1
X2[,5]<-X1[,1]*.2+X1[,2]*.04
fixDependence(X1,X2)
fixDependence(X1,X2,strict=TRUE)
```

---

formula.gam

*GAM formula*

---

## Description

Description of [gam](#) formula (see Details), and how to extract it from a fitted gam object.

## Usage

```
## S3 method for class 'gam'
formula(x, ...)
```

## Arguments

<code>x</code>	fitted model objects of class gam (see <a href="#">gamObject</a> ) as produced by <code>gam()</code> .
<code>...</code>	un-used in this case

## Details

[gam](#) will accept a formula or, with some families, a list of formulae. Other `mgcv` modelling functions will not accept a list. The list form provides a mechanism for specifying several linear predictors, and allows these to share terms: see below.

The formulae supplied to [gam](#) are exactly like that supplied to [glm](#) except that smooth terms, [s](#), [te](#), [ti](#) and [t2](#) can be added to the right hand side (and `.` is not supported in gam formulae).

Smooth terms are specified by expressions of the form:

```
s(x1, x2, ..., k=12, fx=FALSE, bs="tp", by=z, id=1)
```

where `x1`, `x2`, etc. are the covariates which the smooth is a function of, and `k` is the dimension of the basis used to represent the smooth term. If `k` is not specified then basis specific defaults are used. Note that these defaults are essentially arbitrary, and it is important to check that they are not so small that they cause oversmoothing (too large just slows down computation). Sometimes the modelling context suggests sensible values for `k`, but if not informal checking is easy: see [choose.k](#) and [gam.check](#).

`fx` is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by `k` (almost always `k-1`). `bs` indicates the basis to use for the smooth: the built in options are described in [smooth.terms](#), and user defined smooths can be added (see [user.defined.smooth](#)). If `bs` is not supplied then the default "tp" ([tprs](#)) basis is used. `by` can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x, by=z))` would specify a model  $E(y) = f(x)z$  where  $f(\cdot)$  is a smooth function. The `by` option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for 'varying coefficient models': see [gam.models](#). `id`

is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

```
te(x, z, bs=c("tp", "tp"), m=c(2, 3), k=c(5, 10))
```

which would specify a tensor product smooth of the two covariates  $x$  and  $z$  constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. `te` provides further information. `ti` terms are a variant designed to be used as interaction terms when the main effects (and any lower order interactions) are present. `t2` produces tensor product smooths that are the natural low rank analogue of smoothing spline anova models.

`s`, `te`, `ti` and `t2` terms accept an `sp` argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If `sp` is supplied then it over-rides whatever is in the `sp` argument to `gam`, if it is not supplied then it defaults to all negative, but does not over-ride the `sp` argument to `gam`.

Formulae can involve nested or “overlapping” terms such as

```
y ~ s(x) + s(z) + s(x, z) or y ~ s(x, z) + s(z, v)
```

but nested models should really be set up using `ti` terms: see [gam.side](#) for further details and examples.

Smooth terms in a `gam` formula will accept matrix arguments as covariates (and corresponding by variable), in which case a ‘summation convention’ is invoked. Consider the example of `s(X, Z, by=L)` where  $X$ ,  $Z$  and  $L$  are  $n$  by  $m$  matrices. Let  $F$  be the  $n$  by  $m$  matrix that results from evaluating the smooth at the values in  $X$  and  $Z$ . Then the contribution to the linear predictor from the term will be `rowSums(F*L)` (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see [linear.functional.terms](#) for more information and examples (including functional linear models/signal regression).

Note that `gam` allows any term in the model formula to be penalized (possibly by multiple penalties), via the `paraPen` argument. See [gam.models](#) for details and example code.

When several formulae are provided in a list, then they can be used to specify multiple linear predictors for families for which this makes sense (e.g. [mvn](#)). The first formula in the list must include a response variable, but later formulae need not (depending on the requirements of the family). Let the linear predictors be indexed, 1 to  $d$  where  $d$  is the number of linear predictors, and the indexing is in the order in which the formulae appear in the list. It is possible to supply extra formulae specifying that several linear predictors should share some terms. To do this a formula is supplied in which the response is replaced by numbers specifying the indices of the linear predictors which will share the terms specified on the r.h.s. For example `1+3~s(x)+z-1` specifies that linear predictors 1 and 3 will share the terms `s(x)` and `z` (but we don’t want an extra intercept, as this would usually be unidentifiable). Note that it is possible that a linear predictor only includes shared terms: it must still have its own formula, but the r.h.s. would simply be `-1` (e.g. `y ~ -1` or `~ -1`).

## Value

Returns the model formula, `x$formula`. Provided so that `anova` methods print an appropriate description of the model.

formXtViX

*Form component of GAMM covariance matrix***Description**

This is a service routine for `gamm`. Given,  $V$ , an estimated covariance matrix obtained using `extract.lme.cov2` this routine forms a matrix square root of  $X^T V^{-1} X$  as efficiently as possible, given the structure of  $V$  (usually sparse).

**Usage**

```
formXtViX(V, X)
```

**Arguments**

$V$	A data covariance matrix list returned from <code>extract.lme.cov2</code>
$X$	A model matrix.

**Details**

The covariance matrix returned by `extract.lme.cov2` may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

**Value**

A matrix,  $R$  such that `crossprod(R)` gives  $X^T V^{-1} X$ .

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

X <- model.matrix(b, data=ergoStool)
crossprod(formXtViX(V2, X))
t(X)
```

---

fs.test	<i>FELSPLINE test function</i>
---------	--------------------------------

---

## Description

Implements a finite area test function based on one proposed by Tim Ramsay (2002).

## Usage

```
fs.test(x, y, r0=.1, r=.5, l=3, b=1, exclude=TRUE)
fs.boundary(r0=.1, r=.5, l=3, n.theta=20)
```

## Arguments

<code>x, y</code>	Points at which to evaluate the test function.
<code>r0</code>	The test domain is a sort of bent sausage. This is the radius of the inner bend
<code>r</code>	The radius of the curve at the centre of the sausage.
<code>l</code>	The length of an arm of the sausage.
<code>b</code>	The rate at which the function increases per unit increase in distance along the centre line of the sausage.
<code>exclude</code>	Should exterior points be set to NA?
<code>n.theta</code>	How many points to use in a piecewise linear representation of a quarter of a circle, when generating the boundary curve.

## Details

The function details are not given in the source article: but this is pretty close. The function is modified from Ramsay (2002), in that it bulges, rather than being flat: this makes a better test of the smoother.

## Value

`fs.test` returns function evaluations, or NAs for points outside the boundary. `fs.boundary` returns a list of `x, y` points to be jointed up in order to define/draw the boundary.

contour(xm,yn,tru,levels=seq(-5,5,by=.25),add=TRUE)
```

---

full.score

*GCV/UBRE score for use within nlm*

---

## Description

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls `gam.fit` to fit the model, and is usually called by `nlm` to optimize the smoothing parameters.

This is basically a service routine for `gam`, and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see `gam.outer`) when the the outer method is "nlm.fd" (see `gam` argument `optimizer`).

## Usage

```
full.score(sp,G,family,control,gamma,...)
```

## Arguments

<code>sp</code>	The logs of the smoothing parameters
<code>G</code>	a list returned by <code>mgcv::gam.setup</code>
<code>family</code>	The family object for the GAM.
<code>control</code>	a list returned by <code>gam.control</code>
<code>gamma</code>	the degrees of freedom inflation factor (usually 1).
<code>...</code>	other arguments, typically for passing on to <code>gam.fit</code> .

## Value

The value of the GCV/UBRE score, with attribute "full.gam.object" which is the full object returned by `gam.fit`.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

## Description

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM and a variety of other models estimated by a quadratically penalised likelihood type approach (see [family.mgcv](#)). The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Confidence/credible intervals are readily available for any quantity predicted using a fitted model.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC/REML or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate), and users can add smooths. Linear functionals of smooths can also be included in models. For an overview of the smooths available see [smooth.terms](#). For more on specifying models see [gam.models](#), [random.effects](#) and [linear.functional.terms](#). For more on model selection see [gam.selection](#). Do read [gam.check](#) and [choose.k](#).

See [gam](#) from package `gam`, for GAMs via the original Hastie and Tibshirani approach (see details for differences to this implementation).

For very large datasets see [bam](#), for mixed GAM see [gamm](#) and [random.effects](#).

## Usage

```
gam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
    na.action, offset=NULL, method="GCV.Cp",
    optimizer=c("outer", "newton"), control=list(), scale=0,
    select=FALSE, knots=NULL, sp=NULL, min.sp=NULL, H=NULL, gamma=1,
    fit=TRUE, paraPen=NULL, G=NULL, in.out, drop.unused.levels=TRUE, ...)
```

## Arguments

- |                      |   |
|----------------------|---|
| <code>formula</code> | A GAM formula, or a list of formulae (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). These are exactly like the formula for a GLM except that smooth terms, <code>s</code> , <code>te</code> , <code>ti</code> and <code>t2</code> , can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).                           |
| <code>family</code>  | This is a family object specifying the distribution and link to use in fitting etc (see <a href="#">glm</a> and <a href="#">family</a> ). See <a href="#">family.mgcv</a> for a full list of what is available, which goes well beyond exponential family. Note that <code>quasi</code> families actually result in the use of extended quasi-likelihood if <code>method</code> is set to a RE/ML method (McCullagh and Nelder, 1989, 9.6). |
| <code>data</code>    | A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.  |

<code>weights</code>	prior weights on the contribution of the data to the log likelihood. Note that a weight of 2, for example, is equivalent to having made exactly the same observation twice. If you want to reweight the contributions of each datum without changing the overall magnitude of the log likelihood, then you should normalize the weights (e.g. <code>weights &lt;- weights/mean(weights)</code> ).
<code>subset</code>	an optional vector specifying a subset of observations to be used in the fitting process.
<code>na.action</code>	a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
<code>offset</code>	Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula: this conforms to the behaviour of <code>lm</code> and <code>glm</code> .
<code>control</code>	A list of fit control parameters to replace defaults returned by <code>gam.control</code> . Values not set assume default values.
<code>method</code>	The smoothing parameter estimation method. "GCV.Cp" to use GCV for unknown scale parameter and Mallows' Cp/UBRE/AIC for known scale. "GACV.Cp" is equivalent, but using GACV in place of GCV. "REML" for REML estimation, including of unknown scale, "P-REML" for REML estimation, but using a Pearson estimate of the scale. "ML" and "P-ML" are similar, but using maximum likelihood in place of REML. Beyond the exponential family "REML" is the default, and the only other option is "ML".
<code>optimizer</code>	An array specifying the numerical optimization method to use to optimize the smoothing parameter estimation criterion (given by method). "perf" for performance iteration. "outer" for the more stable direct approach. "outer" can use several alternative optimizers, specified in the second element of optimizer: "newton" (default), "bfgs", "optim", "nlm" and "nlm.fd" (the latter is based entirely on finite differenced derivatives and is very slow).
<code>scale</code>	If this is positive then it is taken as the known scale parameter. Negative signals that the scale parameter is unknown. 0 signals that the scale parameter is 1 for Poisson and binomial and unknown otherwise. Note that (RE)ML methods can only work with scale parameter 1 for the Poisson and binomial cases.
<code>select</code>	If this is TRUE then <code>gam</code> can add an extra penalty to each term so that it can be penalized to zero. This means that the smoothing parameter estimation that is part of fitting can completely remove terms from the model. If the corresponding smoothing parameter is estimated as zero then the extra penalty has no effect.
<code>knots</code>	this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the "tp"/"ts" case. Different terms can use different numbers of knots, unless they share a covariate.
<code>sp</code>	A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.
<code>min.sp</code>	Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object,

	will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).
H	A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.
gamma	It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE/AIC score by a constant multiplier. This allows such a multiplier to be supplied.
fit	If this argument is <code>TRUE</code> then <code>gam</code> sets up the model and fits it, but if it is <code>FALSE</code> then the model is set up and an object <code>G</code> containing what would be required to fit is returned. See argument <code>G</code> .
paraPen	optional list specifying any penalties to be applied to parametric model terms. <a href="#">gam.models</a> explains more.
G	Usually <code>NULL</code> , but may contain the object returned by a previous call to <code>gam</code> with <code>fit=FALSE</code> , in which case all other arguments are ignored except for <code>gamma</code> , <code>in.out</code> , <code>scale</code> , <code>control</code> , <code>method</code> <code>optimizer</code> and <code>fit</code> .
in.out	optional list for initializing outer iteration. If supplied then this must contain two elements: <code>sp</code> should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed <code>s.p.s</code> are not used); <code>scale</code> is the typical scale of the GCV/UBRE function, for passing to the outer optimizer, or the the initial value of the scale parameter, if this is to be estimated by RE/ML.
drop.unused.levels	by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.
...	further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code> ).

## Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

$$\log(E(y_i)) = f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables  $y_i \sim \text{Poi}$ , and  $f_1$  and  $f_2$  are smooth functions of covariates  $x_1$  and  $x_2$ . The `log` is an example of a link function.

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex overfitting estimates of  $f_1$  and  $f_2$ . For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggleness’. To control the tradeoff between penalizing wiggleness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The `mgcv` implementation of `gam` represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

`gam` in `mgcv` solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where  $D$  is the deviance,  $n$  the number of data,  $s$  the scale parameter and  $DoF$  the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when  $s$  is known.

Alternatives are GACV, or a Laplace approximation to REML. There is some evidence that the latter may actually be the most effective choice. The main computational challenge solved by the `mgcv` package is to optimize the smoothness selection criteria efficiently and reliably. Various alternative numerical methods are provided which can be set by argument `optimizer`.

Broadly `gam` works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (design matrix) and a set of penalty matrices for the smooth terms. Some linear identifiability constraints are also obtained at this point. The model is fit using `gam.fit`, `gam.fit3` or variants, which are modifications of `glm.fit`. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Reweighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is integrated in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS iteration a penalized weighted least squares problem is solved, and the smoothing parameters of that problem can be estimated by GCV or UBRE. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV, UBRE or REML scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and `gam.fit3` or one of its variants is used in place of `gam.fit`. The default is the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see `smooth.terms` for an overview and `smooth.construct` for how to add smooth classes). The choice of the basis dimension ( $k$  in the `s`, `te`, `ti` and `t2` terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by  $k-1$  or occasionally  $k$ ). Of course the  $k$  should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that `gam` assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end `gam` allows the non smooth model components to be penalized via argument `paraPen` and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in `linear.functional.terms`. `link{family.mgcv}` details what is available beyond GLMs and the exponential family.

Details of the default underlying fitting methods are given in Wood (2011 and 2004). Some alternative methods are discussed in Wood (2000 and 2006).

`gam()` is not a clone of Trevor Hastie's original (as supplied in S-PLUS or package [gam](#)). The major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, (iv) the parametric part of the model can be penalized, (v) simple random effects can be incorporated, and (vi) the facilities for incorporating smooths of more than one variable are different: specifically there are no `lo` smooths, but instead (a) `s` terms can have more than one argument, implying an isotropic smooth and (b) `te`, `ti` or `t2` smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. Splines on the sphere, Duchon splines and Gaussian Markov Random Fields are also available. (vii) Models beyond the exponential family are available. See [gam](#) from package `gam`, for GAMs via the original Hastie and Tibshirani approach.

## Value

If `fit=FALSE` the function returns a list `G` of items needed to fit a GAM, but doesn't actually fit it. Otherwise the function returns an object of class `"gam"` as described in [gamObject](#).

## WARNINGS

The default basis dimensions used for smooth terms are essentially arbitrary, and it should be checked that they are not too small. See [choose.k](#) and [gam.check](#).

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

Front end design inspired by the `S` function of the same name based on the work of Hastie and Tibshirani (1990). Underlying methods owe much to the work of Wahba (e.g. 1990) and Gu (e.g. 2002).

gam.check

*Some diagnostics for a fitted gam model*

## Description

Takes a fitted `gam` object produced by `gam()` and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, some information about the convergence of the smoothness selection optimization, and to run diagnostic tests of whether the basis dimension choices are adequate.

## Usage

```
gam.check(b, old.style=FALSE,
          type=c("deviance", "pearson", "response"),
          k.sample=5000, k.rep=200,
          rep=0, level=.9, rl.col=2, rep.col="gray80", ...)
```

## Arguments

<code>b</code>	a fitted <code>gam</code> object as produced by <code>gam()</code> .
<code>old.style</code>	If you want old fashioned plots, exactly as in Wood, 2006, set to <code>TRUE</code> .
<code>type</code>	type of residuals, see <code>residuals.gam</code> , used in all plots.
<code>k.sample</code>	Above this <code>k</code> testing uses a random sub-sample of data.
<code>k.rep</code>	how many re-shuffles to do to get p-value for <code>k</code> testing.
<code>rep, level, rl.col, rep.col</code>	arguments passed to <code>qq.gam()</code> when <code>old.style</code> is false, see there.
<code>...</code>	extra graphics parameters to pass to plotting functions.

## Details

Checking a fitted `gam` is like checking a fitted `glm`, with two main differences. Firstly, the basis dimensions used for smooth terms need to be checked, to ensure that they are not so small that they force oversmoothing: the defaults are arbitrary. `choose.k` provides more detail, but the diagnostic tests described below and reported by this function may also help. Secondly, fitting may not always be as robust to violation of the distributional assumptions as would be the case for a regular GLM, so slightly more care may be needed here. In particular, the theory of quasi-likelihood implies that if the mean variance relationship is OK for a GLM, then other departures from the assumed distribution are not problematic: GAMs can sometimes be more sensitive. For example, un-modelled overdispersion will typically lead to overfit, as the smoothness selection criterion tries to reduce the scale parameter to the one specified. Similarly, it is not clear how sensitive REML and

ML smoothness selection will be to deviations from the assumed response distribution. For these reasons this routine uses an enhanced residual QQ plot.

This function plots 4 standard diagnostic plots, some smoothing parameter estimation convergence information and the results of tests which may indicate if the smoothing basis dimension for a term is too low.

Usually the 4 plots are various residual plots. For the default optimization methods the convergence information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

The test of whether the basis dimension for a smooth is adequate is based on computing an estimate of the residual variance based on differencing residuals that are near neighbours according to the (numeric) covariates of the smooth. This estimate divided by the residual variance is the `k-index` reported. The further below 1 this is, the more likely it is that there is missed pattern left in the residuals. The `p-value` is computed by simulation: the residuals are randomly re-shuffled `k.rep` times to obtain the null distribution of the differencing variance estimator, if there is no pattern in the residuals. For models fitted to more than `k.sample` data, the tests are based on `k.sample` randomly sampled data. Low `p-values` may indicate that the basis dimension, `k`, has been set too low, especially if the reported `edf` is close to `k`, the maximum possible EDF for the term. Note the disconcerting fact that if the test statistic itself is based on random resampling and the null is true, then the associated `p-values` will of course vary widely from one replicate to the next. Currently smooths of factor variables are not supported and will give an NA `p-value`.

Doubling a suspect `k` and re-fitting is sensible: if the reported `edf` increases substantially then you may have been missing something in the first fit. Of course `p-values` can be low for reasons other than a too low `k`. See `choose.k` for fuller discussion.

The QQ plot produced is usually created by a call to `qq.gam`, and plots deviance residuals against approximate theoretical quantiles of the deviance residual distribution, according to the fitted model. If this looks odd then investigate further using `qq.gam`. Note that residuals for models fitted to binary data contain very little information useful for model checking (it is necessary to find some way of aggregating them first), so the QQ plot is unlikely to be useful in this case.

## Value

A vector of reference quantiles for the residual distribution, if these can be computed.

## Examples

```
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=200)
b<-gam(y~s(x0)+s(x1)+s(x2)+s(x3),data=dat)
plot(b,pages=1)
gam.check(b,pch=19,cex=.3)
```

---

gam.control

Setting GAM fitting defaults

---

## Description

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see [gam](#) arguments `method` and `optimizer`.

## Usage

```
gam.control(nthreads=1,irls.reg=0.0,epsilon = 1e-07, maxit = 200,
            mgcv.tol=1e-7,mgcv.half=15, trace = FALSE,
            rank.tol=.Machine$double.eps^0.5,
            nlm=list(),optim=list(),newton=list(),
            outerPIsteps=0,idLinksBases=TRUE,scalePenalty=TRUE,
            keepData=FALSE,scale.est="fletcher")
```

## Arguments

<code>nthreads</code>	Some parts of some smoothing parameter selection methods (e.g. REML) can use some parallelization in the C code if your R installation supports openMP, and <code>nthreads</code> is set to more than 1. Note that it is usually better to use the number of physical cores here, rather than the number of hyper-threading cores.
<code>irls.reg</code>	For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and <code>irls.reg</code> is the size of the penalty.
<code>epsilon</code>	This is used for judging convergence of the GLM IRLS loop in <a href="#">gam.fit</a> or <a href="#">gam.fit3</a> .
<code>maxit</code>	Maximum number of IRLS iterations to perform.
<code>mgcv.tol</code>	The convergence tolerance parameter to use in GCV/UBRE optimization.
<code>mgcv.half</code>	If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.

<code>trace</code>	Set this to <code>TRUE</code> to turn on diagnostic output.
<code>rank.tol</code>	The tolerance used to estimate the rank of the fitting problem.
<code>nlm</code>	list of control parameters to pass to <code>nlm</code> if this is used for outer estimation of smoothing parameters (not default). See details.
<code>optim</code>	list of control parameters to pass to <code>optim</code> if this is used for outer estimation of smoothing parameters (not default). See details.
<code>newton</code>	list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.
<code>outerPIsteps</code>	The number of performance iteration steps used to initialize outer iteration.
<code>idLinksBases</code>	If smooth terms have their smoothing parameters linked via the <code>id</code> mechanism (see <a href="#">s</a> ), should they also have the same bases. Set this to <code>FALSE</code> only if you are sure you know what you are doing (you should almost surely set <code>scalePenalty</code> to <code>FALSE</code> as well in this case).
<code>scalePenalty</code>	<code>gamm</code> is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accomodate this problem. Probably should be set to <code>FALSE</code> if you are linking smoothing parameters but have set <code>idLinkBases</code> to <code>FALSE</code> .
<code>keepData</code>	Should a copy of the original data argument be kept in the <code>gam</code> object? Strict compatibility with class <code>glm</code> would keep it, but it wastes space to do so.
<code>scale.est</code>	How to estimate the scale parameter for exponential family models estimated by outer iteration. See <a href="#">gam.scale</a> .

## Details

Outer iteration using `newton` is controlled by the list `newton` with the following elements: `conv.tol` (default `1e-6`) is the relative convergence tolerance; `maxNstep` is the maximum length allowed for an element of the Newton search direction (default `5`); `maxSstep` is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default `2`); `maxHalf` is the maximum number of step halvings to permit before giving up (default `30`).

If outer iteration using `nlm` is used for fitting, then the control list `nlm` stores control arguments for calls to routine `nlm`. The list has the following named elements: (i) `ndigit` is the number of significant digits in the GCV/UBRE score - by default this is worked out from `epsilon`; (ii) `gradtol` is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to `10*epsilon`; (iii) `stepmax` is the maximum allowable log smoothing parameter step - defaults to `2`; (iv) `steptol` is the minimum allowable step length - defaults to `1e-4`; (v) `iterlim` is the maximum number of optimization steps allowed - defaults to `200`; (vi) `check.analyticals` indicates whether the built in exact derivative calculations should be checked numerically - defaults to `FALSE`. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using `optim` is controlled using list `optim`, which currently has one element: `factr` which takes default value `1e7`.

*GAM convergence and performance issues*

---

### Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The default fitting options, specified by [gam](#) arguments `method` and `optimizer`, opt for certainty of convergence over speed of fit. In the Generalized Additive Model case it means using ‘outer’ iteration in preference to ‘performance iteration’: see [gam.outer](#) for details.

It is possible for the default ‘outer’ iteration to fail when finding initial smoothing parameters using a few steps of performance iteration (if you get a convergence failure message from `magic` when outer iterating, then this is what has happened): lower `outerPIsteps` in [gam.control](#) to fix this.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the `"bfgs"` method option in [gam](#) argument `optimizer`: this can be faster than the default. (ii) Change the `optimizer` argument to [gam](#) so that ‘performance iteration’ is used in place of the default outer iteration. Usually performance iteration converges well and it can sometimes be quicker than the default outer iteration. (iii) For large datasets it may be worth changing the smoothing basis to use `bs="cr"` (see [s](#) for details) for 1-d smooths, and to use `te` smooths in place of `s` smooths for smooths of more than one variable. This is because the default thin plate regression spline basis `"tp"` is costly to set up for large datasets (much over 1000 data, say). (iv) consider using [bam](#).

If the GAM estimation process fails to converge when using performance iteration, then switch to outer iteration via the `optimizer` argument of [gam](#). If it still fails, try increasing the number of IRLS iterations (see [gam.control](#)) or perhaps experiment with the convergence tolerance.

If you still have problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in [gam.control](#), there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the `min.sp` argument of [gam](#): this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of `s` and `te` model terms: this obviously changes the model being fitted somewhat; (iii) introduce a small regularization term into the fitting via the `irls.reg` argument of [gam.control](#): this option obviously changes the nature of the fit somewhat, since parameter estimates are pulled towards zero by doing this.

Usually, a major contributor to fitting difficulties is that the model is a very poor description of the data.

gam.fit

---

*GAM P-IRLS estimation with GCV/UBRE smoothness estimation*

---

**Description**

This is an internal function of package `mgcv`. It is a modification of the function `glm.fit`, designed to be called from `gam`. The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine `magic`. For further information on usage see code for `gam`. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see `gam.control`). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

**Usage**

```
gam.fit(G, start = NULL, etastart = NULL,
        mustart = NULL, family = gaussian(),
        control = gam.control(), gamma=1,
        fixedSteps=(control$maxit+1), ...)
```

**Arguments**

<code>G</code>	An object of the type returned by <code>gam</code> when <code>fit=FALSE</code> .
<code>start</code>	Initial values for the model coefficients.
<code>etastart</code>	Initial values for the linear predictor.
<code>mustart</code>	Initial values for the expected response.
<code>family</code>	The family object, specifying the distribution and link to use.
<code>control</code>	Control option list as returned by <code>gam.control</code> .
<code>gamma</code>	Parameter which can be increased to up the cost of each effective degree of freedom in the GCV or AIC/UBRE objective.
<code>fixedSteps</code>	How many steps to take: useful when only using this routine to get rough starting values for other methods.
<code>...</code>	Other arguments: ignored.

**Value**

A list of fit information.

**Author(s)**

## Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC, GCV, GACV, REML or ML score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the smoothness selection scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC/REML score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for [gam](#).

## Usage

```
gam.fit3(x, y, sp, Eb, UrS=list(),
         weights = rep(1, nobs), start = NULL, etastart = NULL,
         mustart = NULL, offset = rep(0, nobs), U1 = diag(ncol(x)),
         Mp = -1, family = gaussian(), control = gam.control(),
         intercept = TRUE, deriv=2, gamma=1, scale=1,
         printWarn=TRUE, scoreType="REML", null.coef=rep(0, ncol(x)),
         pearson.extra=0, dev.extra=0, n.true=-1, Sl=NULL, ...)
```

## Arguments

- |    |  |
|----|--|
| x  | The model matrix for the GAM (or any penalized GLM).                                   |
| y  | The response variable.   |
| sp | The log smoothing parameters.  |
| Eb | A balanced version of the total penalty matrix: used for numerical rank determination. |

UrS	List of square root penalties premultiplied by transpose of orthogonal basis for the total penalty.
weights	prior weights for fitting.
start	optional starting parameter guesses.
etastart	optional starting values for the linear predictor.
mustart	optional starting values for the mean.
offset	the model offset
U1	An orthogonal basis for the range space of the penalty — required for ML smoothness estimation only.
Mp	The dimension of the total penalty null space — required for ML smoothness estimation only.
family	the family - actually this routine would never be called with <code>gaussian()</code>
control	control list as returned from <code>glm.control</code>
intercept	does the model have an intercept, TRUE or FALSE
deriv	Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.
gamma	The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.
scale	The scale parameter - needed for the UBRE/AIC score.
printWarn	Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization.
scoreType	specifies smoothing parameter selection criterion to use.
null.coef	coefficients for a model which gives some sort of upper bound on deviance. This allows immediate divergence problems to be controlled.
pearson.extra	Extra component to add to numerator of pearson statistic in P-REML/P-ML smoothness selection criteria.
dev.extra	Extra component to add to deviance for REML/ML type smoothness selection criteria.
n.true	Number of data to assume in smoothness selection criteria. $\leq 0$ indicates that it should be the number of rows of X.
S1	A smooth list suitable for passing to <code>gam.fit5</code> .
...	Other arguments: ignored.

### Details

This routine is basically `glm.fit` with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by use of the implicit function theorem and (iii) derivatives of the GAM GCV, UBRE/AIC, REML or ML scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O’Sullivan et al. (1986), and is here termed ‘outer’ iteration.

Note that use of non-standard families with this routine requires modification of the families as described in [fix.family.link](#).

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

The routine has been modified from `glm.fit` in R 2.0.1, written by the R core (see [glm.fit](#) for further credits).

### Description

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let  $y_i$  denote an independent random variable with mean  $\mu_i$  and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = \mathbf{X}_i\beta + f_1(x_{1i}, x_{2i}) + f_2(x_{3i}) + L_i f_3(x_4) + \dots$$

where  $g$  is a known smooth monotonic ‘link’ function,  $\mathbf{X}_i\beta$  is the parametric part of the linear predictor, the  $x_j$  are predictor variables, the  $f_j$  are smooth functions and  $L_i$  is some linear functional of  $f_3$ . There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. `gam`

always applies such constraints unless there is a `by` variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for `gam`. Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page therefore concentrates on the model formula for `gam`.

## Models with simple smooth terms

Consider the example model.

$$g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})$$

where the response variables  $y_i$  has expectation  $\mu_i$  and  $g$  is a link function.

The `gam` formula for this would be

```
y ~ x1 + x2 + s(x3) + s(x4, x5).
```

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in [s](#) and [te](#), and further discussion of basis dimension choice can be found in [choose.k](#). For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

```
y ~ x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=25, fx=TRUE).
```

The above assumes that  $x_4$  and  $x_5$  are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see [te](#)).

```
y ~ x1 + x2 + s(x3) + te(x4, x5)
```

would generate a tensor product smooth of  $x_4$  and  $x_5$ . By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

```
y ~ x1 + x2 + s(x3) + te(x4, x5, bs=c("cr", "ps"), k=c(6, 7))
```

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

## Nested terms/functional ANOVA

Sometimes it is interesting to specify smooth models with a main effects + interaction structure such as

$$E(y_i) = f_1(x_i) + f_2(z_i) + f_3(x_i, z_i)$$

or

$$E(y_i) = f_1(x_i) + f_2(z_i) + f_3(v_i) + f_4(x_i, z_i) + f_5(z_i, v_i) + f_6(z_i, v_i) + f_7(x_i, z_i, v_i)$$

for example. Such models should be set up using `ti` terms in the model formula. For example:

```
y ~ ti(x) + ti(z) + ti(x, z), or
```

```
y ~ ti(x) + ti(z) + ti(v) + ti(x, z) + ti(x, v) + ti(z, v) + ti(x, z, v).
```

The `ti` terms produce interactions with the component main effects excluded appropriately. (There is in fact no need to use `ti` terms for the main effects here, `s` terms could also be used.)

`gam` allows nesting (or ‘overlap’) of `te` and `s` smooths, and automatically generates side conditions to make such models identifiable, but the resulting models are much less stable and interpretable than those constructed using `ti` terms.

### ‘by’ variables

by variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The `s` and `te` terms used to specify smooths accept an argument `by`, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a `by` variable is numeric, then its  $i^{th}$  element multiplies the  $i^{th}$  row of the model matrix corresponding to the smooth term concerned.

Factor smooth interactions (see also `factor.smooth.interaction`). If a `by` variable is a `factor` then it generates an indicator vector for each level of the factor, unless it is an `ordered` factor. In the non-ordered case, the model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter). `ordered` `by` variables are handled in the same way, except that no smooth is generated for the first level of the ordered factor (see `b3` example below). This is useful for setting up identifiable models when the same smooth occurs more than once in a model, with different factor `by` variables.

As an example, consider the model

$$E(y_i) = \beta_0 + f(x_i)z_i$$

where  $f$  is a smooth function, and  $z_i$  is a numeric variable. The appropriate formula is:

```
y ~ s(x, by=z)
```

- the `by` argument ensures that the smooth function gets multiplied by covariate  $z$ . Note that when using factor `by` variables, centering constraints are applied to the smooths, which usually means that the `by` variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor `by` variables.

`by` variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a `by` variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the `by` variable is a constant vector, or, (ii) for a matrix `by` variable, `L, if  $L \% \text{rep}(1, \text{ncol}(L))$  is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly, and that constraint has an attribute "always.apply".`

### Linking smooths with ‘id’

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the `id` argument to `s` or `te` terms. Smooths which share an `id` will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an `id` have the same basis functions as the first smooth occurring with that `id`. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under ‘linear functional terms’.

As an example suppose that  $E(y_i) \equiv \mu_i$  and

$$g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i})$$

but that  $f_1$  and  $f_3$  should have the same smoothing parameters (and  $x_2$  and  $x_3$  are on different scales). Then the `gam` formula

```
y ~ s(x1, id=1) + te(x_2, x3) + s(x4, id=1)
```

would achieve the desired result. `id` can be numbers or character strings. Giving an `id` to a term with a factor `by` variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term `ids` are not supported by `gamm`.

### Linear functional terms

General linear functional terms have a long history in the spline literature including in the penalized GLM context (see e.g. Wahba 1990). Such terms encompass varying coefficient models/ geographic regression, functional GLMs (i.e. GLMs with functional predictors), GLASS models, etc, and allow smoothing with respect to aggregated covariate values, for example.

Such terms are implemented in `mgcv` using a simple ‘summation convention’ for smooth terms: If the covariates of a smooth are supplied as matrices, then summation of the evaluated smooth over the columns of the matrices is implied. Each covariate matrix and any `by` variable matrix must be of the same dimension. Consider, for example the term

`s(X, Z, by=L)`

where `X`, `Z` and `L` are  $n \times p$  matrices. Let  $f$  denote the thin plate regression spline specified. The resulting contribution to the  $i^{\text{th}}$  element of the linear predictor is

$$\sum_{j=1}^p L_{ij} f(X_{ij}, Z_{ij})$$

If no `L` is supplied then all its elements are taken as 1. In R code terms, let `F` denote the  $n \times p$  matrix obtained by evaluating the smooth at the values in `X` and `Z`. Then the contribution of the term to the linear predictor is `rowSums(L * F)` (note that it’s element by element multiplication here!).

The summation convention applies to `te` terms as well as `s` terms. More details and examples are provided in [linear.functional.terms](#).

### Random effects

Random effects can be added to `gam` models using `s(..., bs="re")` terms (see [smooth.construct.re.smooth.spec](#)), or the `paraPen` argument to `gam` covered below. See [gam.vcomp.random.effects](#) and [smooth.construct.re.smooth.spec](#) for further details. An alternative is to use the approach of `gamm`.

### Penalizing the parametric terms

In case the ability to add smooth classes, smooth identities, `by` variables and the summation convention are still not sufficient to implement exactly the penalized GLM that you require, `gam` also allows you to penalize the parametric terms in the model formula. This is mostly useful in allowing one or more matrix terms to be included in the formula, along with a sequence of quadratic penalty matrices for each.

Suppose that you have set up a model matrix `X`, and want to penalize the corresponding coefficients,  $\beta$  with two penalties  $\beta^T \mathbf{S}_1 \beta$  and  $\beta^T \mathbf{S}_2 \beta$ . Then something like the following would be appropriate:

```
gam(y ~ X - 1, paraPen=list(X=list(S1, S2)))
```

The `paraPen` argument should be a list with elements having names corresponding to the terms being penalized. Each element of `paraPen` is itself a list, with optional elements `L`, `rank` and `sp`: all other elements must be penalty matrices. If present, `rank` is a vector giving the rank of each penalty matrix (if absent this is determined numerically). `L` is a matrix that maps underlying log smoothing parameters to the log smoothing parameters that actually multiply the individual quadratic penalties: taken as the identity if not supplied. `sp` is a vector of (underlying) smoothing

parameter values: positive values are taken as fixed, negative to signal that the smoothing parameter should be estimated. Taken as all negative if not supplied.

An obvious application of `paraPen` is to incorporate random effects, and an example of this is provided below. In this case the supplied penalty matrices will be (generalized) inverse covariance matrices for the random effects — i.e. precision matrices. The final estimate of the covariance matrix corresponding to one of these penalties is given by the (generalized) inverse of the penalty matrix multiplied by the estimated scale parameter and divided by the estimated smoothing parameter for the penalty. For example, if you use an identity matrix to penalize some coefficients that are to be viewed as i.i.d. Gaussian random effects, then their estimated variance will be the estimated scale parameter divided by the estimate of the smoothing parameter, for this penalty. See the ‘rail’ example below.

P-values for penalized parametric terms should be treated with caution. If you must have them, then use the option `freq=TRUE` in `anova.gam` and `summary.gam`, which will tend to give reasonable results for random effects implemented this way, but not for terms with a rank deficient penalty (or penalties with a wide eigen-spectrum).

```

## Description

Estimation of GAM smoothing parameters is most stable if optimization of the smoothness selection score (GCV, GACV, UBRE/AIC, REML, ML etc) is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine optimizes a smoothness selection score in this way. Basically the score is evaluated for each trial set of smoothing parameters by estimating the GAM for those smoothing parameters. The score is minimized w.r.t. the parameters numerically, using `newton` (default), `bfgs`, `optim` or `nlm`. Exact (first and second) derivatives of the score can be used by fitting with `gam.fit3`. This improves efficiency and reliability relative to relying on finite difference derivatives.

Not normally called directly, but rather a service routine for `gam`.

## Usage

```
gam.outer(lsp, fscale, family, control, method, optimizer,
          criterion, scale, gamma, G, ...)
```

## Arguments

<code>lsp</code>	The log smoothing parameters.
<code>fscale</code>	Typical scale of the GCV or UBRE/AIC score.
<code>family</code>	the model family.
<code>control</code>	control argument to pass to <code>gam.fit</code> if pure finite differencing is being used.
<code>method</code>	method argument to <code>gam</code> defining the smoothness criterion to use (but depending on whether or not scale known).
<code>optimizer</code>	The argument to <code>gam</code> defining the numerical optimization method to use.
<code>criterion</code>	Which smoothness selection criterion to use. One of "UBRE", "GCV", "GACV", "REML" or "P-REML".
<code>scale</code>	Supplied scale parameter. Positive indicates known.
<code>gamma</code>	The degree of freedom inflation factor for the GCV/UBRE/AIC score.
<code>G</code>	List produced by <code>mgcv:::gam.setup</code> , containing most of what's needed to actually fit a GAM.
<code>...</code>	other arguments, typically for passing on to <code>gam.fit3</code> (ultimately).

## Details

See Wood (2008) for full details on ‘outer iteration’.

gam.scale

*Scale parameter estimation in GAMs***Description**

Scale parameter estimation in `gam` depends on the type of family. For extended families then the RE/ML estimate is used. For conventional exponential families, estimated by the default outer iteration, the scale estimator can be controlled using argument `scale.est` in `gam.control`. The options are "fletcher" (default), "pearson" or "deviance". The Pearson estimator is the (weighted) sum of squares of the pearson residuals, divided by the effective residual degrees of freedom. The Fletcher (2012) estimator is an improved version of the Pearson estimator. The deviance estimator simply substitutes deviance residuals for Pearson residuals.

Usually the Pearson estimator is recommended for GLMs, since it is asymptotically unbiased. However, it can also be unstable at finite sample sizes, if a few Pearson residuals are very large. For example, a very low Poisson mean with a non zero count can give a huge Pearson residual, even though the deviance residual is much more modest. The Fletcher (2012) estimator is designed to reduce these problems.

For performance iteration the Pearson estimator is always used.

`gamm` uses the estimate of the scale parameter from the underlying call to `lme`. `bam` uses the REML estimator if the method is "fREML". Otherwise the estimator is a Pearson estimator.

gam.selection

*Generalized Additive Model Selection***Description**

This page is intended to provide some more information on how to select GAMs. In particular, it gives a brief overview of smoothness selection, and then discusses how this can be extended to select inclusion/exclusion of terms. Hypothesis testing approaches to the latter problem are also discussed.

### Smoothness selection criteria

Given a model structure specified by a gam model formula, `gam()` attempts to find the appropriate smoothness for each applicable model term using prediction error criteria or likelihood based methods. The prediction error criteria used are Generalized (Approximate) Cross Validation (GCV or GACV) when the scale parameter is unknown or an Un-Biased Risk Estimator (UBRE) when it is known. UBRE is essentially scaled AIC (Generalized case) or Mallows' Cp (additive model case). GCV and UBRE are covered in Craven and Wahba (1979) and Wahba (1990). Alternatively REML of maximum likelihood (ML) may be used for smoothness selection, by viewing the smooth components as random effects (in this case the variance component for each smooth random effect will be given by the scale parameter divided by the smoothing parameter — for smooths with multiple penalties, there will be multiple variance components). The `method` argument to `gam` selects the smoothness selection criterion.

Automatic smoothness selection is unlikely to be successful with few data, particularly with multiple terms to be selected. In addition GCV and UBRE/AIC score can occasionally display local minima that can trap the minimisation algorithms. GCV/UBRE/AIC scores become constant with changing smoothing parameters at very low or very high smoothing parameters, and on occasion these 'flat' regions can be separated from regions of lower score by a small 'lip'. This seems to be the most common form of local minimum, but is usually avoidable by avoiding extreme smoothing parameters as starting values in optimization, and by avoiding big jumps in smoothing parameters while optimizing. Never the less, if you are suspicious of smoothing parameter estimates, try changing fit method (see `gam` arguments `method` and `optimizer`) and see if the estimates change, or try changing some or all of the smoothing parameters 'manually' (argument `sp` of `gam`, or `sp` arguments to `s` or `te`).

REML and ML are less prone to local minima than the other criteria, and may therefore be preferable.

### Automatic term selection

Unmodified smoothness selection by GCV, AIC, REML etc. will not usually remove a smooth from a model. This is because most smoothing penalties view some space of (non-zero) functions as 'completely smooth' and once a term is penalized heavily enough that it is in this space, further penalization does not change it.

However it is straightforward to modify smooths so that under heavy penalization they are penalized to the zero function and thereby 'selected out' of the model. There are two approaches.

The first approach is to modify the smoothing penalty with an additional shrinkage term. Smooth classes `cs.smooth` and `tp.rs.smooth` (specified by "`cs`" and "`ts`" respectively) have smoothness penalties which include a small shrinkage component, so that for large enough smoothing parameters the smooth becomes identically zero. This allows automatic smoothing parameter selection methods to effectively remove the term from the model altogether. The shrinkage component of the penalty is set at a level that usually makes negligible contribution to the penalization of the model, only becoming effective when the term is effectively 'completely smooth' according to the conventional penalty.

The second approach leaves the original smoothing penalty unchanged, but constructs an additional penalty for each smooth, which penalizes only functions in the null space of the original penalty (the 'completely smooth' functions). Hence, if all the smoothing parameters for a term tend to infinity, the term will be selected out of the model. This latter approach is more expensive computationally, but has the advantage that it can be applied automatically to any smooth term. The `select` argument to `gam` turns on this method.

In fact, as implemented, both approaches operate by eigen-decomposing the original penalty matrix. A new penalty is created on the null space: it is the matrix with the same eigenvectors as

the original penalty, but with the originally positive eigenvalues set to zero, and the originally zero eigenvalues set to something positive. The first approach just adds a multiple of this penalty to the original penalty, where the multiple is chosen so that the new penalty can not dominate the original. The second approach treats the new penalty as an extra penalty, with its own smoothing parameter.

Of course, as with all model selection methods, some care must be taken to ensure that the automatic selection is sensible, and a decision about the effective degrees of freedom at which to declare a term ‘negligible’ has to be made.

### Interactive term selection

In general the most logically consistent method to use for deciding which terms to include in the model is to compare GCV/UBRE/ML scores for models with and without the term (REML scores should not be used to compare models with different fixed effects structures). When UBRE is the smoothness selection method this will give the same result as comparing by AIC (the AIC in this case uses the model EDF in place of the usual model DF). Similarly, comparison via GCV score and via AIC seldom yields different answers. Note that the negative binomial with estimated `theta` parameter is a special case: the GCV score is not informative, because of the `theta` estimation scheme used. More generally the score for the model with a smooth term can be compared to the score for the model with the smooth term replaced by appropriate parametric terms. Candidates for replacement by parametric terms are smooth terms with estimated degrees of freedom close to their minimum possible.

Candidates for removal can also be identified by reference to the approximate p-values provided by `summary.gam`, and by looking at the extent to which the confidence band for an estimated term includes the zero function. It is perfectly possible to perform backwards selection using p-values in the usual way: that is by sequentially dropping the single term with the highest non-significant p-value from the model and re-fitting, until all terms are significant. This suffers from the same problems as stepwise procedures for any GLM/LM, with the additional caveat that the p-values are only approximate. If adopting this approach, it is probably best to use ML smoothness selection.

Note that GCV and UBRE are not appropriate for comparing models using different families: in that case AIC should be used.

### Caveats/platitudes

Formal model selection methods are only appropriate for selecting between reasonable models. If formal model selection is attempted starting from a model that simply doesn’t fit the data, then it is unlikely to provide meaningful results.

The more thought is given to appropriate model structure up front, the more successful model selection is likely to be. Simply starting with a hugely flexible model with ‘everything in’ and hoping that automatic selection will find the right structure is not often successful.

gam.side

*Identifiability side conditions for a GAM*

---

## Description

GAM formulae with repeated variables may only correspond to identifiable models given some side conditions. This routine works out appropriate side conditions, based on zeroing redundant parameters. It is called from `mgcv:::gam.setup` and is not intended to be called by users.

The method identifies nested and repeated variables by their names, but numerically evaluates which constraints need to be imposed. Constraints are always applied to smooths of more variables in preference to smooths of fewer variables. The numerical approach allows appropriate constraints to be applied to models constructed using any smooths, including user defined smooths.

## Usage

```
gam.side(sm, Xp, tol=.Machine$double.eps^.5, with.pen=FALSE)
```

## Arguments

<code>sm</code>	A list of smooth objects as returned by <a href="#">smooth.construct</a> .
<code>Xp</code>	The model matrix for the strictly parametric model components.
<code>tol</code>	The tolerance to use when assessing linear dependence of smooths.
<code>with.pen</code>	Should the computation of dependence consider the penalties or not. Doing so will lead to fewer constraints.

## Details

Models such as  $y \sim s(x) + s(z) + s(x, z)$  can be estimated by `gam`, but require identifiability constraints to be applied, to make them identifiable. This routine does this, effectively setting redundant parameters to zero. When the redundancy is between smooths of lower and higher numbers of variables, the constraint is always applied to the smooth of the higher number of variables.

Dependent smooths are identified symbolically, but which constraints are needed to ensure identifiability of these smooths is determined numerically, using `fixDependence`. This makes the routine rather general, and not dependent on any particular basis.

`Xp` is used to check whether there is a constant term in the model (or columns that can be linearly combined to give a constant). This is because centred smooths can appear independent, when they would be dependent if there is a constant in the model, so dependence testing needs to take account of this.

## Value

A list of smooths, with model matrices and penalty matrices adjusted to automatically impose the required constraints. Any smooth that has been modified will have an attribute `"del.index"`, listing the columns of its model matrix that were deleted. This index is used in the creation of prediction matrices for the term.

plot(b, pages=1)

## Simulate data with real interaction...
dat <- gamSim(2, n=500, scale=.1)
old.par <- par(mfrow=c(2, 2))

## a fully nested tensor product example (bad idea)
b <- gam(y ~ s(x, bs="cr", k=6) + s(z, bs="cr", k=6) + te(x, z, k=6),
        data=dat$data)
plot(b)

old.par <- par(mfrow=c(2, 2))
## A fully nested tensor product example, done properly,
## so that gam.side is not needed to ensure identifiability.
## ti terms are designed to produce interaction smooths
## suitable for adding to main effects (we could also have
## used s(x) and s(z) without a problem, but not s(z, x)
## or te(z, x)).
b <- gam(y ~ ti(x, k=6) + ti(z, k=6) + ti(x, z, k=6),
```

```

        data=dat$data)
plot(b)

par(old.par)
rm(dat)

```

gam.vcomp

*Report gam smoothness estimates as variance components*

## Description

GAMs can be viewed as mixed models, where the smoothing parameters are related to variance components. This routine extracts the estimated variance components associated with each smooth term, and if possible returns confidence intervals on the standard deviation scale.

## Usage

```
gam.vcomp(x, rescale=TRUE, conf.lev=.95)
```

## Arguments

<code>x</code>	a fitted model object of class <code>gam</code> as produced by <code>gam()</code> .
<code>rescale</code>	the penalty matrices for smooths are rescaled before fitting, for numerical stability reasons, if <code>TRUE</code> this rescaling is reversed, so that the variance components are on the original scale.
<code>conf.lev</code>	when the smoothing parameters are estimated by REML or ML, then confidence intervals for the variance components can be obtained from large sample likelihood results. This gives the confidence level to work at.

## Details

The (pseudo) inverse of the penalty matrix penalizing a term is proportional to the covariance matrix of the term's coefficients, when these are viewed as random. For single penalty smooths, it is possible to compute the variance component for the smooth (which multiplies the inverse penalty matrix to obtain the covariance matrix of the smooth's coefficients). This variance component is given by the scale parameter divided by the smoothing parameter.

This routine computes such variance components, for `gam` models, and associated confidence intervals, if smoothing parameter estimation was likelihood based. Note that variance components are also returned for tensor product smooths, but that their interpretation is not so straightforward.

The routine is particularly useful for model fitted by `gam` in which random effects have been incorporated.

## Value

Either a vector of variance components for each smooth term (as standard deviations), or a matrix. The first column of the matrix gives standard deviations for each term, while the subsequent columns give lower and upper confidence bounds, on the same scale.

For models in which there are more smoothing parameters than actually estimated (e.g. if some were fixed, or smoothing parameters are linked) then a list is returned. The `vc` element is as above, the `all` element is a vector of variance components for all the smoothing parameters (estimated + fixed or replicated).

The routine prints a table of estimated standard deviations and confidence limits, if these can be computed, and reports the numerical rank of the covariance matrix.

gam.vcomp(mod)
```

### Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters. These functions evaluate the GCV/UBRE/AIC score of a GAM model, given smoothing parameters, in a manner suitable for use by [optim](#) or [nlm](#). Not normally called directly, but rather service routines for [gam.outer](#).

**Usage**

```
gam2objective(lsp, args, ...)
gam2derivative(lsp, args, ...)
```

**Arguments**

<code>lsp</code>	The log smoothing parameters.
<code>args</code>	List of arguments required to call <code>gam.fit3</code> .
<code>...</code>	Other arguments for passing to <code>gam.fit3</code> .

**Details**

`gam2objective` and `gam2derivative` are functions suitable for calling by `optim`, to evaluate the GCV/UBRE/AIC score and its derivatives w.r.t. log smoothing parameters.

`gam4objective` is an equivalent to `gam2objective`, suitable for optimization by `nlm` - derivatives of the GCV/UBRE/AIC function are calculated and returned as attributes.

The basic idea of optimizing smoothing parameters ‘outer’ to the P-IRLS loop was first proposed in O’Sullivan et al. (1986).

**See Also**

`gam.fit3`, `gam`, `magic`

**Description**

Fits the specified generalized additive mixed model (GAMM) to data, by a call to `lme` in the normal errors identity link case, or by a call to `gammPQL` (a modification of `glmPQL` from the MASS library) otherwise. In the latter case estimates are only approximately MLEs. The routine is typically slower than `gam`, and not quite as numerically robust.

To use `lme4` in place of `nlme` as the underlying fitting engine, see `gamm4` from package `gamm4`.

Smooths are specified as in a call to `gam` as part of the fixed effects model formula, but the wiggly components of the smooth are treated as random effects. The random effects structures and correlation structures available for `lme` are used to specify other random effects and correlations.

It is assumed that the random effects and correlation structures are employed primarily to model residual correlation in the data and that the prime interest is in inference about the terms in the fixed effects model formula including the smooths. For this reason the routine calculates a posterior covariance matrix for the coefficients of all the terms in the fixed effects formula, including the smooths.

To use this function effectively it helps to be quite familiar with the use of `gam` and `lme`.

### Usage

```
gamm(formula, random=NULL, correlation=NULL, family=gaussian(),
      data=list(), weights=NULL, subset=NULL, na.action, knots=NULL,
      control=list(niterEM=0, optimMethod="L-BFGS-B"),
      niterPQL=20, verbosePQL=TRUE, method="ML", drop.unused.levels=TRUE, ...)
```

### Arguments

<code>formula</code>	A GAM formula (see also <code>formula.gam</code> and <code>gam.models</code> ). This is like the formula for a <code>glm</code> except that smooth terms ( <code>s</code> and <code>te</code> ) can be added to the right hand side of the formula. Note that <code>ids</code> for smooths and fixed smoothing parameters are not supported.
<code>random</code>	The (optional) random effects structure as specified in a call to <code>lme</code> : only the <code>list</code> form is allowed, to facilitate manipulation of the random effects structure within <code>gamm</code> in order to deal with smooth terms. See example below.
<code>correlation</code>	An optional <code>corStruct</code> object (see <code>corClasses</code> ) as used to define correlation structures in <code>lme</code> . Any grouping factors in the formula for this object are assumed to be nested within any random effect grouping factors, without the need to make this explicit in the formula (this is slightly different to the behaviour of <code>lme</code> ). This is a GEE approach to correlation in the generalized case. See examples below.
<code>family</code>	A family as used in a call to <code>glm</code> or <code>gam</code> . The default <code>gaussian</code> with identity link causes <code>gamm</code> to fit by a direct call to <code>lme</code> provided there is no offset term, otherwise <code>gammPQL</code> is used.
<code>data</code>	A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>gamm</code> is called.
<code>weights</code>	In the generalized case, weights with the same meaning as <code>glm</code> weights. An <code>lme</code> type weights argument may only be used in the identity link gaussian case, with no offset (see documentation for <code>lme</code> for details of how to use such an argument).
<code>subset</code>	an optional vector specifying a subset of observations to be used in the fitting process.
<code>na.action</code>	a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
<code>knots</code>	this is an optional list containing user specified knot values to be used for basis construction. Different terms can use different numbers of knots, unless they share a covariate.

<code>control</code>	A list of fit control parameters for <code>lme</code> to replace the defaults returned by <code>lmeControl</code> . Note the setting for the number of EM iterations used by <code>lme</code> : smooths are set up using custom <code>pdMat</code> classes, which are currently not supported by the EM iteration code. If you supply a list of control values, it is advisable to include <code>niterEM=0</code> , as well, and only increase from 0 if you want to perturb the starting values used in model fitting (usually to worse values!). The <code>optimMethod</code> option is only used if your version of R does not have the <code>nlminb</code> optimizer function.
<code>niterPQL</code>	Maximum number of PQL iterations (if any).
<code>verbosePQL</code>	Should PQL report its progress as it goes along?
<code>method</code>	Which of "ML" or "REML" to use in the Gaussian additive mixed model case when <code>lme</code> is called directly. Ignored in the generalized case (or if the model has an offset), in which case <code>gammPQL</code> is used.
<code>drop.unused.levels</code>	by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.
<code>...</code>	further arguments for passing on e.g. to <code>lme</code>

## Details

The Bayesian model of spline smoothing introduced by Wahba (1983) and Silverman (1985) opens up the possibility of estimating the degree of smoothness of terms in a generalized additive model as variances of the wiggly components of the smooth terms treated as random effects. Several authors have recognised this (see Wang 1998; Ruppert, Wand and Carroll, 2003) and in the normal errors, identity link case estimation can be performed using general linear mixed effects modelling software such as `lme`. In the generalized case only approximate inference is so far available, for example using the Penalized Quasi-Likelihood approach of Breslow and Clayton (1993) as implemented in `glmmPQL` by Venables and Ripley (2002). One advantage of this approach is that it allows correlated errors to be dealt with via random effects or the correlation structures available in the `nlme` library (using correlation structures beyond the strictly additive case amounts to using a GEE approach to fitting).

Some details of how GAMs are represented as mixed models and estimated using `lme` or `gammPQL` in `gamm` can be found in Wood (2004, 2006a,b). In addition `gamm` obtains a posterior covariance matrix for the parameters of all the fixed effects and the smooth terms. The approach is similar to that described in Lin & Zhang (1999) - the covariance matrix of the data (or pseudodata in the generalized case) implied by the weights, correlation and random effects structure is obtained, based on the estimates of the parameters of these terms and this is used to obtain the posterior covariance matrix of the fixed and smooth effects.

The bases used to represent smooth terms are the same as those used in `gam`, although adaptive smoothing bases are not available. Prediction from the returned `gam` object is straightforward using `predict.gam`, but this will set the random effects to zero. If you want to predict with random effects set to their predicted values then you can adapt the prediction code given in the examples below.

In the event of `lme` convergence failures, consider modifying `option(mgcv.vc.logrange)`: reducing it helps to remove indefiniteness in the likelihood, if that is the problem, but too large a reduction can force over or undersmoothing. See [notExp2](#) for more information on this option. Failing that, you can try increasing the `niterEM` option in `control`: this will perturb the starting values used in fitting, but usually to values with lower likelihood! Note that this version of `gamm` works best with R 2.2.0 or above and `nlme`, 3.1-62 and above, since these use an improved optimizer.

**Value**

Returns a list with two items:

<code>gam</code>	an object of class <code>gam</code> , less information relating to GCV/UBRE model selection. At present this contains enough information to use <code>predict</code> , <code>summary</code> and <code>print</code> methods and <code>vis.gam</code> , but not to use e.g. the <code>anova</code> method function to compare models.
<code>lme</code>	the fitted model object returned by <code>lme</code> or <code>gammPQL</code> . Note that the model formulae and grouping structures may appear to be rather bizarre, because of the manner in which the GAMM is split up and the calls to <code>lme</code> and <code>gammPQL</code> are constructed.

**WARNINGS**

`gamm` performs poorly with binary data, since it uses PQL. It is better to use `gam` with `s(..., bs="re")` terms, or `gamm4`.

`gamm` assumes that you know what you are doing! For example, unlike `glmmPQL` from MASS it will return the complete `lme` object from the working model at convergence of the PQL iteration, including the ‘log likelihood’, even though this is not the likelihood of the fitted GAMM.

The routine will be very slow and memory intensive if correlation structures are used for the very large groups of data. e.g. attempting to run the spatial example in the examples section with many 1000’s of data is definitely not recommended: often the correlations should only apply within clusters that can be defined by a grouping factor, and provided these clusters do not get too huge then fitting is usually possible.

Models must contain at least one random effect: either a smooth with non-zero smoothing parameter, or a random effect specified in argument `random`.

`gamm` is not as numerically stable as `gam`: an `lme` call will occasionally fail. See details section for suggestions, or try the ‘`gamm4`’ package.

`gamm` is usually much slower than `gam`, and on some platforms you may need to increase the memory available to R in order to use it with large data sets (see [mem.limits](#)).

Note that the weights returned in the fitted GAM object are dummy, and not those used by the PQL iteration: this makes partial residual plots look odd.

Note that the `gam` object part of the returned object is not complete in the sense of having all the elements defined in [gamObject](#) and does not inherit from `glm`: hence e.g. multi-model `anova` calls will not work.

The parameterization used for the smoothing parameters in `gamm`, bounds them above and below by an effective infinity and effective zero. See [notExp2](#) for details of how to change this.

Linked smoothing parameters and adaptive smoothing are not supported.

gamObject

*Fitted gam object*

## Description

A fitted GAM object returned by function `gam` and of class "gam" inheriting from classes "glm" and "lm". Method functions `anova`, `logLik`, `influence`, `plot`, `predict`, `print`, `residuals` and `summary` exist for this class.

All compulsory elements of "glm" and "lm" objects are present, but the fitting method for a GAM is different to a linear model or GLM, so that the elements relating to the QR decomposition of the model matrix are absent.

**Value**

A gam object has the following elements:

<code>aic</code>	AIC of the fitted model: bear in mind that the degrees of freedom used to calculate this are the effective degrees of freedom of the model, and the likelihood is evaluated at the maximum of the penalized likelihood in most cases, not at the MLE.
<code>assign</code>	Array whose elements indicate which model term (listed in <code>pterms</code> ) each parameter relates to: applies only to non-smooth terms.
<code>boundary</code>	did parameters end up at boundary of parameter space?
<code>call</code>	the matched call (allows <code>update</code> to be used with gam objects, for example).
<code>cmX</code>	column means of the model matrix (with elements corresponding to smooths set to zero ) — useful for componentwise CI calculation.
<code>coefficients</code>	the coefficients of the fitted model. Parametric coefficients are first, followed by coefficients for each spline term in turn.
<code>control</code>	the gam control list used in the fit.
<code>converged</code>	indicates whether or not the iterative fitting method converged.
<code>data</code>	the original supplied data argument (for class "glm" compatibility). Only included if <code>gam</code> control argument element <code>keepData</code> is set to TRUE (default is FALSE).
<code>db.drho</code>	matrix of first derivatives of model coefficients w.r.t. log smoothing parameters.
<code>deviance</code>	model deviance (not penalized deviance).
<code>df.null</code>	null degrees of freedom.
<code>df.residual</code>	effective residual degrees of freedom of the model.
<code>edf</code>	estimated degrees of freedom for each model parameter. Penalization means that many of these are less than 1.
<code>edf1</code>	similar, but using alternative estimate of EDF. Useful for testing.
<code>edf2</code>	if estimation is by ML or REML then an edf that accounts for smoothing parameter uncertainty can be computed, this is it. <code>edf1</code> is a heuristic upper bound for <code>edf2</code> .
<code>family</code>	family object specifying distribution and link used.
<code>fitted.values</code>	fitted model predictions of expected value for each datum.
<code>formula</code>	the model formula.
<code>full.sp</code>	full array of smoothing parameters multiplying penalties (excluding any contribution from <code>min.sp</code> argument to <code>gam</code> ). May be larger than <code>sp</code> if some terms share smoothing parameters, and/or some smoothing parameter values were supplied in the <code>sp</code> argument of <code>gam</code> .
<code>F</code>	Degrees of freedom matrix. This may be removed at some point, and should probably not be used.
<code>gcv.ubre</code>	The minimized smoothing parameter selection score: GCV, UBRE(AIC), GACV, negative log marginal likelihood or negative log restricted likelihood.
<code>hat</code>	array of elements from the leading diagonal of the ‘hat’ (or ‘influence’) matrix. Same length as response data vector.
<code>iter</code>	number of iterations of P-IRLS taken to get convergence.

<code>linear.predictors</code>	fitted model prediction of link function of expected value for each datum.
<code>method</code>	One of "GCV" or "UBRE", "REML", "P-REML", "ML", "P-ML", "PQL", "lme.ML" or "lme.REML", depending on the fitting criterion used.
<code>mgcv.conv</code>	A list of convergence diagnostics relating to the "magic" parts of smoothing parameter estimation - this will not be very meaningful for pure "outer" estimation of smoothing parameters. The items are: <code>full.rank</code> , The apparent rank of the problem given the model matrix and constraints; <code>rank</code> , The numerical rank of the problem; <code>fully.converged</code> , TRUE is multiple GCV/UBRE converged by meeting convergence criteria and FALSE if method stopped with a steepest descent step failure; <code>hess.pos.def</code> Was the hessian of the GCV/UBRE score positive definite at smoothing parameter estimation convergence?; <code>iter</code> How many iterations were required to find the smoothing parameters? <code>score.calls</code> , and how many times did the GCV/UBRE score have to be evaluated?; <code>rms.grad</code> , root mean square of the gradient of the GCV/UBRE score at convergence.
<code>min.edf</code>	Minimum possible degrees of freedom for whole model.
<code>model</code>	model frame containing all variables needed in original model fit.
<code>na.action</code>	The <code>na.action</code> used in fitting.
<code>nsdf</code>	number of parametric, non-smooth, model terms including the intercept.
<code>null.deviance</code>	deviance for single parameter model.
<code>offset</code>	model offset.
<code>optimizer</code>	optimizer argument to <code>gam</code> , or "magic" if it's a pure additive model.
<code>outer.info</code>	If 'outer' iteration has been used to fit the model (see <code>gam</code> argument <code>optimizer</code> ) then this is present and contains whatever was returned by the optimization routine used (currently <code>nlm</code> or <code>optim</code> ).
<code>paraPen</code>	If the <code>paraPen</code> argument to <code>gam</code> was used then this provides information on the parametric penalties. NULL otherwise.
<code>pred.formula</code>	one sided formula containing variables needed for prediction, used by <code>predict.gam</code>
<code>prior.weights</code>	prior weights on observations.
<code>pterms</code>	terms object for strictly parametric part of model.
<code>R</code>	Factor R from QR decomposition of weighted model matrix, unpivoted to be in same column order as model matrix (so need not be upper triangular).
<code>rank</code>	apparent rank of fitted model.
<code>reml.scale</code>	The scale (RE)ML scale parameter estimate, if (P-)(RE)ML used for smoothness estimation.
<code>residuals</code>	the working residuals for the fitted model.
<code>rV</code>	If present, <code>rV**%t(rV)*sig2</code> gives the estimated Bayesian covariance matrix.
<code>scale</code>	when present, the scale (as <code>sig2</code> )
<code>scale.estimated</code>	TRUE if the scale parameter was estimated, FALSE otherwise.
<code>sig2</code>	estimated or supplied variance/scale parameter.

<code>smooth</code>	list of smooth objects, containing the basis information for each term in the model formula in the order in which they appear. These smooth objects are what gets returned by the <code>smooth.construct</code> objects.
<code>sp</code>	estimated smoothing parameters for the model. These are the underlying smoothing parameters, subject to optimization. For the full set of smoothing parameters multiplying the penalties see <code>full.sp</code> . Divide the scale parameter by the smoothing parameters to get, variance components, but note that this is not valid for smooths that have used rescaling to improve conditioning.
<code>terms</code>	<code>terms</code> object of <code>model</code> model frame.
<code>var.summary</code>	A named list of summary information on the predictor variables. If a parametric variable is a matrix, then the summary is a one row matrix, containing the observed data value closest to the column median, for each matrix column. If the variable is a factor the then summary is the modal factor level, returned as a factor, with levels corresponding to those of the data. For numerics and matrix arguments of smooths, the summary is the mean, nearest observed value to median and maximum, as a numeric vector. Used by <code>vis.gam</code> , in particular.
<code>Ve</code>	frequentist estimated covariance matrix for the parameter estimators. Particularly useful for testing whether terms are zero. Not so useful for CI's as smooths are usually biased.
<code>Vp</code>	estimated covariance matrix for the parameters. This is a Bayesian posterior covariance matrix that results from adopting a particular Bayesian model of the smoothing process. Particularly useful for creating credible/confidence intervals.
<code>Vc</code>	Under ML or REML smoothing parameter estimation it is possible to correct the covariance matrix <code>Vp</code> for smoothing parameter uncertainty. This is the corrected version.
<code>weights</code>	final weights used in IRLS iteration.
<code>y</code>	response data.

## WARNINGS

This model object is different to that described in Chambers and Hastie (1993) in order to allow smoothing parameter estimation etc.

gamSim*Simulate example data for GAMs*

---

**Description**

Function used to simulate data sets to illustrate the use of [gam](#) and [gamm](#). Mostly used in help files to keep down the length of the example code sections.

**Usage**

```
gamSim(eg=1, n=400, dist="normal", scale=2, verbose=TRUE)
```

**Arguments**

eg	numeric value specifying the example required.
n	number of data to simulate.
dist	character string which may be used to specify the distribution of the response.
scale	Used to set noise level.
verbose	Should information about simulation type be printed?

**Details**

See the source code for exactly what is simulated in each case.

1. Gu and Wahba 4 univariate term example.
2. A smooth function of 2 variables.
3. Example with continuous by variable.
4. Example with factor by variable.
5. An additive example plus a factor variable.
6. Additive + random effect.
7. As 1 but with correlated covariates.

**Value**

Depends on `eg`, but usually a dataframe, which may also contain some information on the underlying truth. Sometimes a list with more items, including a data frame for model fitting. See source code or helpfile examples where the function is used for further information.

```

gaulss

*Gaussian location-scale model family***Description**

The `gaulss` family implements Gaussian location scale additive models in which the mean and the inverse of the standard deviation can depend on additive smooth predictors. Useable only with `gam`, the linear predictors are specified via a list of formulae.

**Usage**

```
gaulss(link=list("identity", "logb"), b=0.01)
```

**Arguments**

<code>link</code>	two item list specifying the link for the mean and the standard deviation. See details.
<code>b</code>	The minumum standard deviation, for the "logb" link.

**Details**

Used with `gam` to fit Gaussian location - scale models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the mean on the right hand side. The second is one sided, specifying the linear predictor for the standard deviation on the right hand side.

Link functions "identity", "inverse", "log" and "sqrt" are available for the mean. For the standard deviation only the "logb" link is implemented:  $\eta = \log(\sigma - b)$  and  $\sigma = b + \exp(\eta)$ . This link is designed to avoid singularities in the likelihood caused by the standard deviation tending to zero.

The fitted values for this family will be a two column matrix. The first column is the mean, and the second column is the inverse of the standard deviation. Predictions using `predict.gam` will also produce 2 column matrices for type "link" and "response".

The null deviance reported for this family is the sum of squares of the difference between the response and the mean response divided by the standard deviation of the response according to the model. The deviance is the sum of squares of residuals divided by model standard deviations.

**Value**

An object inheriting from class `general.family`.

**Examples**

```
library(mgcv); library(MASS)
b <- gam(list(accel~s(times, k=20, bs="ad"), ~s(times)),
           data=mcycle, family=gaulss())
summary(b)
plot(b, pages=1, scale=0)
```

---

`get.var`*Get named variable or evaluate expression from list or data.frame*

---

### Description

This routine takes a text string and a data frame or list. It first sees if the string is the name of a variable in the data frame/ list. If it is then the value of this variable is returned. Otherwise the routine tries to evaluate the expression within the data.frame/list (but nowhere else) and if successful returns the result. If neither step works then `NULL` is returned. The routine is useful for processing gam formulae. If the variable is a matrix then it is coerced to a numeric vector, by default.

### Usage

```
get.var(txt, data, vecMat=TRUE)
```

### Arguments

<code>txt</code>	a text string which is either the name of a variable in <code>data</code> or when parsed is an expression that can be evaluated in <code>data</code> . It can also be neither in which case the function returns <code>NULL</code> .
<code>data</code>	A data frame or list.
<code>vecMat</code>	Should matrices be coerced to numeric vectors?

### Value

The evaluated variable or `NULL`. May be coerced to a numeric vector if it's a matrix.

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

### References

### Examples

```
require(mgcv)
y <- 1:4; dat<-data.frame(x=5:10)
get.var("x", dat)
get.var("y", dat)
get.var("x==6", dat)
dat <- list(X=matrix(1:6,3,2))
get.var("X", dat)
```

---

in.out

---

*Which of a set of points lie within a polygon defined region*

---

### Description

Tests whether each of a set of points lie within a region defined by one or more (possibly nested) polygons. Points count as ‘inside’ if they are interior to an odd number of polygons.

### Usage

```
in.out (bnd, x)
```

### Arguments

bnd	A two column matrix, the rows of which define the vertices of polygons defining the boundary of a region. Different polygons should be separated by an NA row, and the polygons are assumed closed.
x	A two column matrix. Each row is a point to test for inclusion in the region defined by bnd.

### Details

The algorithm works by counting boundary crossings (using compiled C code).

### Value

A logical vector of length `nrow(x)`. TRUE if the corresponding row of `x` is inside the boundary and FALSE otherwise.

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

### References

<http://www.maths.bath.ac.uk/~sw283/>

### Examples

```
library(mgcv)
data(columb.polys)
bnd <- columb.polys[[2]]
plot(bnd, type="n")
polygon(bnd)
x <- seq(7.9, 8.7, length=20)
y <- seq(13.7, 14.3, length=20)
gr <- as.matrix(expand.grid(x, y))
inside <- in.out(bnd, gr)
points(gr, col=as.numeric(inside)+1)
```

---

influence.gam	<i>Extract the diagonal of the influence/hat matrix for a GAM</i>
---------------	---

---

**Description**

Extracts the leading diagonal of the influence matrix (hat matrix) of a fitted gam object.

**Usage**

```
## S3 method for class 'gam'  
influence(model, ...)
```

**Arguments**

model	fitted model objects of class gam as produced by gam().
...	un-used in this case

**Details**

Simply extracts hat array from fitted model. (More may follow!)

**Value**

An array (see above).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

[gam](#)

---

initial.sp	<i>Starting values for multiple smoothing parameter estimation</i>
------------	--

---

**Description**

Finds initial smoothing parameter guesses for multiple smoothing parameter estimation. The idea is to find values such that the estimated degrees of freedom per penalized parameter should be well away from 0 and 1 for each penalized parameter, thus ensuring that the values are in a region of parameter space where the smoothing parameter estimation criterion is varying substantially with smoothing parameter value.

**Usage**

```
initial.sp(X, S, off, expensive=FALSE, XX=FALSE)
```

Arguments

X	is the model matrix.
S	is a list of of penalty matrices. $S[[i]]$ is the $i$ th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of $S[[i]]$ occupies element $off[i], off[i]$ of the $i$ th penalty matrix. Each $S[[i]]$ must be positive semi-definite.
off	is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving $S[[i]]$ .
expensive	if TRUE then the overall amount of smoothing is adjusted so that the average degrees of freedom per penalized parameter is exactly 0.5: this is numerically costly.
XX	if TRUE then X contains $X^T X$ , rather than $X$ .

Details

Basically uses a crude approximation to the estimated degrees of freedom per model coefficient, to try and find smoothing parameters which bound these e.d.f.'s away from 0 and 1.  
Usually only called by [magic](#) and [gam](#).

Value

An array of initial smoothing parameter estimates.

inSide	<i>Are points inside boundary?</i>
--------	------------------------------------

---

Description

Assesses whether points are inside a boundary. The boundary must enclose the domain, but may include islands.

Usage

```
inSide(bnd, x, y)
```

Arguments

bnd	This should have two equal length columns with names matching whatever is supplied in x and y. This may contain several sections of boundary separated by NA. Alternatively bnd may be a list, each element of which contains 2 columns named as above. See below for details.
x	x co-ordinates of points to be tested.
y	y co-ordinates of points to be tested.

## Details

Segments of boundary are separated by NAs, or are in separate list elements. The boundary coordinates are taken to define nodes which are joined by straight line segments in order to create the boundary. Each segment is assumed to define a closed loop, and the last point in a segment will be assumed to be joined to the first. Loops must not intersect (no test is made for this).

The method used is to count how many times a line, in the y-direction from a point, crosses a boundary segment. An odd number of crossings defines an interior point. Hence in geographic applications it would be usual to have an outer boundary loop, possibly with some inner 'islands' completely enclosed in the outer loop.

The routine calls compiled C code and operates by an exhaustive search for each point in  $x$ ,  $y$ .

## Value

The function returns a logical array of the same dimension as  $x$  and  $y$ . TRUE indicates that the corresponding  $x$ ,  $y$  point lies inside the boundary.

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

## References

<http://www.maths.bath.ac.uk/~sw283/>

## Examples

```
require(mgcv)
m <- 300; n <- 150
xm <- seq(-1,4,length=m); yn<-seq(-1,1,length=n)
x <- rep(xm,n); y<-rep(yn,rep(m,n))
er <- matrix(fs.test(x,y),m,n)
bnd <- fs.boundary()
in.bnd <- inSide(bnd,x,y)
plot(x,y,col=as.numeric(in.bnd)+1,pch=".")
lines(bnd$x,bnd$y,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=".")
## check boundary details ...
plot(x,y,col=as.numeric(in.bnd)+1,pch=".",ylim=c(-1,0),xlim=c(3,3.5))
lines(bnd$x,bnd$y,col=3)
points(x,y,col=as.numeric(in.bnd)+1,pch=".")
```

## Description

This is an internal function of package mgcv. It is a service routine for gam which splits off the strictly parametric part of the model formula, returning it as a formula, and interprets the smooth parts of the model formula.

Not normally called directly.

**Usage**

```
interpret.gam(gf)
```

**Arguments**

`gf` A GAM formula as supplied to [gam](#) or [gamm](#), or a list of such formulae, as supplied for some [gam](#) families.

**Value**

An object of class `split.gam.formula` with the following items:

<code>pf</code>	A model formula for the strictly parametric part of the model.
<code>pfok</code>	TRUE if there is a <code>pf</code> formula.
<code>smooth.spec</code>	A list of class <code>xx.smooth.spec</code> objects where <code>xx</code> depends on the basis specified for the term. (These can be passed to smooth constructor method functions to actually set up penalties and bases.)
<code>full.formula</code>	An expanded version of the model formula in which the options are fully expanded, and the options do not depend on variables which might not be available later.
<code>fake.formula</code>	A formula suitable for use in evaluating a model frame.
<code>response</code>	Name of the response variable.

jagam

*Just Another Gibbs Additive Modeller: JAGS support for mgcv.*

---

**Description**

Facilities to auto-generate model specification code and associated data to simulate with GAMs in JAGS (or BUGS). This is useful for inference about models with complex random effects structure best coded in JAGS. It is a very inefficient approach to making inferences about standard GAMs. The idea is that `jagam` generates template JAGS code, and associated data, for the smooth part of the model. This template is then directly edited to include other stochastic components. After simulation with the resulting model, facilities are provided for plotting and prediction with the model smooth components.

## Usage

```
jagam(formula, family=gaussian, data=list(), file, weights=NULL, na.action,
offset=NULL, knots=NULL, sp=NULL, drop.unused.levels=TRUE,
control=gam.control(), centred=TRUE, sp.prior = "gamma", diagonalize=FALSE)

sim2jam(sam, pregam, edf.type=2, burnin=0)
```

## Arguments

<code>formula</code>	A GAM formula (see <a href="#">formula.gam</a> and also <a href="#">gam.models</a> ). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> , <code>te</code> , <code>ti</code> and <code>t2</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).
<code>family</code>	This is a family object specifying the distribution and link function to use. See <a href="#">glm</a> and <a href="#">family</a> for more details. Currently only gaussian, poisson, binomial and Gamma families are supported, but the user can easily modify the assumed distribution in the JAGS code.
<code>data</code>	A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>jagam</code> is called.
<code>file</code>	Name of the file to which JAGS model specification code should be written. See <a href="#">setwd</a> for setting and querying the current working directory.
<code>weights</code>	prior weights on the data.
<code>na.action</code>	a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
<code>offset</code>	Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in <code>formula</code> : this conforms to the behaviour of <code>lm</code> and <code>glm</code> .
<code>control</code>	A list of fit control parameters to replace defaults returned by <a href="#">gam.control</a> . Any control parameters not supplied stay at their default values. little effect on <code>jagam</code> .
<code>knots</code>	this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code> ). See <a href="#">tprs</a> for what happens in the " <code>tp</code> " / " <code>ts</code> " case. Different terms can use different numbers of knots, unless they share a covariate.
<code>sp</code>	A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula (without forgetting null space penalties). Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.
<code>drop.unused.levels</code>	by default unused levels are dropped from factors before fitting. For some smooths involving factor variables you might want to turn this off. Only do so if you know what you are doing.

<code>centred</code>	Should centring constraints be applied to the smooths, as is usual with GAMS? Only set this to <code>FALSE</code> if you know exactly what you are doing. If <code>FALSE</code> there is a (usually global) intercept for each smooth.
<code>sp.prior</code>	"gamma" or "log.uniform" prior for the smoothing parameters? Do check that the default parameters are appropriate for your model in the JAGS code.
<code>diagonalize</code>	Should smooths be re-parameterized to have i.i.d. Gaussian priors (where possible)? For Gaussian data this allows efficient conjugate samplers to be used, and it can also work well with GLMs if the JAGS "glm" module is loaded, but otherwise it is often better to update smoothers blockwise, and not do this.
<code>sam</code>	jags sample object, containing at least fields <code>b</code> (coefficients) and <code>rho</code> (log smoothing parameters). May also contain field <code>mu</code> containing monitored expected response.
<code>pregam</code>	standard <code>mgcv</code> GAM setup data, as returned in <code>jagam</code> return list.
<code>edf.type</code>	Since EDF is not uniquely defined and may be affected by the stochastic structure added to the JAGS model file, 3 options are offered. See details.
<code>burnin</code>	the amount of burn in to discard from the simulation chains. Limited to .9 of the chain length.

## Details

Smooths are easily incorporated into JAGS models using multivariate normal priors on the smooth coefficients. The smoothing parameters and smoothing penalty matrices directly specify the prior multivariate normal precision matrix. Normally a smoothing penalty does not correspond to a full rank precision matrix, implying an improper prior inappropriate for Gibbs sampling. To rectify this problem the null space penalties suggested in Marra and Wood (2011) are added to the usual penalties.

In an additive modelling context it is usual to centre the smooths, to avoid the identifiability issues associated with having an intercept for each smooth term (in addition to a global intercept). Under Gibbs sampling with JAGS it is technically possible to omit this centring, since we anyway force propriety on the priors, and this propriety implies formal model identifiability. However, in most situations this formal identifiability is rather artificial and does not imply statistically meaningful identifiability. Rather it serves only to massively inflate confidence intervals, since the multiple intercept terms are not identifiable from the data, but only from the prior. By default then, `jagam` imposes standard GAM identifiability constraints on all smooths. The `centred` argument does allow you to turn this off, but it is not recommended. If you do set `centred=FALSE` then chain convergence and mixing checks should be particularly stringent.

The final technical issue for model setup is the setting of initial conditions for the coefficients and smoothing parameters. The approach taken is to take the default initial smoothing parameter values used elsewhere by `mgcv`, and to take a single PIRLS fitting step with these smoothing parameters in order to obtain starting values for the smooth coefficients. In the setting of fully conjugate updating the initial values of the coefficients are not critical, and good results are obtained without supplying them. But in the usual setting in which slice sampling is required for at least some of the updates then very poor results can sometimes be obtained without initial values, as the sampler simply fails to find the region of the posterior mode.

The `sim2jam` function takes the partial gam object (`pregam`) from `jagam` along with simulation output in standard `rjags` form and creates a reduced version of a gam object, suitable for plotting and prediction of the model's smooth components. `sim2gam` computes effective degrees of freedom for each smooth, but it should be noted that there are several possibilities for doing this in the context of a model with a complex random effects structure. The simplest approach (`edf.type=0`) is to compute the degrees of freedom that the smooth would have had if it had

been part of an unweighted Gaussian additive model. One might choose to use this option if the model has been modified so that the response distribution and/or link are not those that were specified to `jagam`. The second option is (`edf.type=1`) uses the edf that would have been computed by `gam` had it produced these estimates - in the context in which the JAGS model modifications have all been about modifying the random effects structure, this is equivalent to simply setting all the random effects to zero for the effective degrees of freedom calculation. The default option (`edf.type=2`) is to base the EDF on the sample covariance matrix,  $V_p$ , of the model coefficients. If the simulation output (`sim`) includes a `mu` field, then this will be used to form the weight matrix  $W$  in  $XWX = t(X) \%*\%W\%*\%X$ , where the EDF is computed from `rowSums(Vp*XWX)*scale`. If `mu` is not supplied then it is estimated from the the model matrix  $X$  and the mean of the simulated coefficients, but the resulting  $W$  may not be strictly compatible with the  $V_p$  matrix in this case. In the situation in which the fitted model is very different in structure from the regression model of the template produced by `jagam` then the default option may make no sense, and indeed it may be best to use option 0.

### Value

For `jagam` a three item list containing

<code>pregam</code>	standard <code>mgcv</code> GAM setup data.
<code>jags.data</code>	list of arguments to be supplied to JAGS containing information referenced in model specification.
<code>jags.ini</code>	initialization data for smooth coefficients and smoothing parameters.

For `sim2jam` an object of class "jam": a partial version of an `mgcv gamObject`, suitable for plotting and predicting.

### WARNINGS

Gibb's sampling is a very slow inferential method for standard GAMs. It is only likely to be worthwhile when complex random effects structures are required above what is possible with direct GAMM methods.

Check that the parameters of the priors on the parameters are fit for your purpose.

pd <- data.frame(x0=c(.5,.6),x1=c(.4,.2),x2=c(.8,.4),x3=c(.1,.1))
fv <- predict(jam,newdata=pd)

## End(Not run)

```

ldTweedie

*Log Tweedie density evaluation*

## Description

A function to evaluate the log of the Tweedie density for variance powers between 1 and 2, inclusive. Also evaluates first and second derivatives of log density w.r.t. its scale parameter,  $\phi$ , and  $p$ , or w.r.t.  $\rho = \log(\phi)$  and  $\theta$  where  $p = (a+b \cdot \exp(\theta)) / (1 + \exp(\theta))$ .

## Usage

```
ldTweedie(y, mu=y, p=1.5, phi=1, rho=NA, theta=NA, a=1.001, b=1.999)
```

## Arguments

<code>y</code>	values at which to evaluate density.
<code>mu</code>	corresponding means (either of same length as <code>y</code> or a single value).
<code>p</code>	the variance of <code>y</code> is proportional to its mean to the power <code>p</code> . <code>p</code> must be between 1 and 2. 1 is Poisson like (exactly Poisson if <code>phi=1</code> ), 2 is gamma.
<code>phi</code>	The scale parameter. Variance of <code>y</code> is $\phi \cdot \mu^p$ .
<code>rho</code>	optional log scale parameter. Over-rides <code>phi</code> if <code>theta</code> also supplied.
<code>theta</code>	parameter such that $p = (a+b \cdot \exp(\theta)) / (1 + \exp(\theta))$ . Over-rides <code>p</code> if <code>rho</code> also supplied.
<code>a</code>	lower limit parameter used in definition of <code>p</code> from <code>theta</code> .
<code>b</code>	upper limit parameter used in definition of <code>p</code> from <code>theta</code> .

## Details

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ .

`ldTweedie` is based on the series evaluation method of Dunn and Smyth (2005). Without the restriction on  $p$  the calculation of Tweedie densities is less straightforward. If you really need this case then the `tweedie` package is the place to start.

The `rho`, `theta` parameterization is useful for optimization of  $p$  and  $\phi$ , in order to keep  $p$  bounded well away from 1 and 2, and  $\phi$  positive. The derivatives near  $p=1$  tend to infinity.

**Value**

A matrix with 6 columns. The first is the log density of  $y$  (log probability if  $p=1$ ). The second and third are the first and second derivatives of the log density w.r.t.  $\phi$ . 4th and 5th columns are first and second derivative w.r.t.  $p$ , final column is second derivative w.r.t.  $\phi$  and  $p$ .

If `rho` and `theta` were supplied then derivatives are w.r.t. these.

  fy <- exp(ldTweedie(y,mu=2,p=p[i],phi=phi)[,1])
  lines(y,fy,col=i)
}
```

---

linear.functional.terms

*Linear functionals of a smooth in GAMs*

---

**Description**

`gam` allows the response variable to depend on linear functionals of smooth terms. Specifically dependencies of the form

$$g(\mu_i) = \dots + \sum_j L_{ij} f(x_{ij}) + \dots$$

are allowed, where the  $x_{ij}$  are covariate values and the  $L_{ij}$  are fixed weights. i.e. the response can depend on the weighted sum of the same smooth evaluated at different covariate values. This allows, for example, for the response to depend on the derivatives or integrals of a smooth (approximated by finite differencing or quadrature, respectively). It also allows dependence on predictor functions (sometimes called ‘signal regression’).

The mechanism by which this is achieved is to supply matrices of covariate values to the model smooth terms specified by `s` or `te` terms in the model formula. Each column of the covariate matrix gives rise to a corresponding column of predictions from the smooth. Let the resulting matrix of evaluated smooth values be  $F$  ( $F$  will have the same dimension as the covariate matrices). In the absence of a `by` variable then these columns are simply summed and added to the linear predictor. i.e. the contribution of the term to the linear predictor is `rowSums(F)`. If a `by` variable is present then it must be a matrix,  $L$ , say, of the same dimension as  $F$  (and the covariate matrices), and it contains the weights  $L_{ij}$  in the summation given above. So in this case the contribution to the linear predictor is `rowSums(L*F)`.

Note that if a `L1` (i.e. `rowSums(L)`) is a constant vector, or there is no `by` variable then the smooth will automatically be centred in order to ensure identifiability. Otherwise it will not be. Note also that for centred smooths it can be worth replacing the constant term in the model with `rowSums(L)` in order to ensure that predictions are automatically on the right scale.

When predicting from the model it is not necessary to provide matrix covariate and `by` variable values. For example to simply examine the underlying smooth function one would use vectors of covariate values and vector `by` variables, with the `by` variable and equivalent of `L1`, above, set to vectors of ones.

## A "signal" regression example...#
#####

rf <- function(x=seq(0,1,length=100)) {
  ## generates random functions...
  m <- ceiling(runif(1)*5) ## number of components
  f <- x*0;
  mu <- runif(m,min(x),max(x)); sig <- (runif(m)+.5)*(max(x)-min(x))/10
  for (i in 1:m) f <- f+ dnorm(x,mu[i],sig[i])
  f
}

x <- seq(0,1,length=100) ## evaluation points

## example functional predictors...
par(mfrow=c(3,3)); for (i in 1:9) plot(x,rf(x),type="l",xlab="x")

## simulate 200 functions and store in rows of L...
L <- matrix(NA,200,100)
for (i in 1:200) L[i,] <- rf() ## simulate the functional predictors

f2 <- function(x) { ## the coefficient function
  (0.2*x^11*(10*(1-x))^6+10*(10*x)^3*(1-x)^10)/10
}

f <- f2(x) ## the true coefficient function

y <- L%*%f + rnorm(200)*20 ## simulated response data

## Now fit the model  $E(y) = L\%*f(x)$  where  $f$  is a smooth function.
## The summation convention is used to evaluate smooth at each value
## in matrix  $X$  to get matrix  $F$ , say. Then  $\text{rowSum}(L*F)$  gives  $E(y)$ .

## create matrix of eval points for each function. Note that
## 'smoothCon' is smart and will recognize the duplication...
X <- matrix(x,200,100,byrow=TRUE)

b <- gam(y~s(X,by=L,k=20))
par(mfrow=c(1,1))
plot(b,shade=TRUE); lines(x,f,col=2)
```

logLik.gam

*Log likelihood for a fitted GAM, for AIC*

## Description

Function to extract the log-likelihood for a fitted `gam` model (note that the models are usually fitted by penalized likelihood maximization). Used by [AIC](#).

## Usage

```
## S3 method for class 'gam'
logLik(object,...)
```

**Arguments**

object	fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .
...	un-used in this case

**Details**

Modification of `logLik.glm` which corrects the degrees of freedom for use with `gam` objects.

The function is provided so that [AIC](#) functions correctly with `gam` objects, and uses the appropriate degrees of freedom (accounting for penalization). Note, when using `AIC` for penalized models, that the degrees of freedom are the effective degrees of freedom and not the number of parameters, and the model maximizes the penalized likelihood, not the actual likelihood. (See e.g. Hastie and Tibshirani, 1990, section 6.8.3 and also Wood 2008),

By default this routine uses a definition of the effective degrees of freedom that includes smoothing parameter uncertainty, if this is available (i.e. if smoothing parameter selection is by some variety of marginal likelihood).

**Value**

Standard `logLik` object: see [logLik](#).

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)> based directly on `logLik.glm`

`ls.size`

*Size of list elements*

---

**Description**

Produces a named array giving the size, in bytes, of the elements of a list.

**Usage**

```
ls.size(x)
```

**Arguments**

x	A list.
---	---------

**Value**

A numeric vector giving the size in bytes of each element of the list `x`. The elements of the array have the same names as the elements of the list. If `x` is not a list then its size in bytes is returned, un-named.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

<http://www.maths.bath.ac.uk/~sw283/>

**Examples**

```
library(mgcv)
b <- list(M=matrix(runif(100),10,10),quote=
"The world is ruled by idiots because only an idiot would want to rule the world.",
fam=binomial())
ls.size(b)
```

---

magic

---

*Stable Multiple Smoothing Parameter Estimation by GCV or UBRE*

---

**Description**

Function to efficiently estimate smoothing parameters in generalized ridge regression problems with multiple (quadratic) penalties, by GCV or UBRE. The function uses Newton's method in multi-dimensions, backed up by steepest descent to iteratively adjust the smoothing parameters for each penalty (one penalty may have a smoothing parameter fixed at 1).

For maximal numerical stability the method is based on orthogonal decomposition methods, and attempts to deal with numerical rank deficiency gracefully using a truncated singular value decomposition approach.

**Usage**

```
magic(y,X,sp,S,off,L=NULL,lsp0=NULL,rank=NULL,H=NULL,C=NULL,
w=NULL,gamma=1,scale=1,gcv=TRUE,ridge.parameter=NULL,
control=list(tol=1e-6,step.half=25,rank.tol=
.Machine$double.eps^0.5),extra.rss=0,n.score=length(y),nthreads=1)
```

**Arguments**

<code>y</code>	is the response data vector.
<code>X</code>	is the model matrix (more columns than rows are allowed).
<code>sp</code>	is the array of smoothing parameters. The vector <code>L*log(sp) + lsp0</code> contains the logs of the smoothing parameters that actually multiply the penalty matrices stored in <code>S</code> ( <code>L</code> is taken as the identity if <code>NULL</code> ). Any <code>sp</code> values that are negative are autoinitialized, otherwise they are taken as supplying starting values. A supplied starting value will be reset to a default starting value if the gradient of the GCV/UBRE score is too small at the supplied value.

<code>S</code>	is a list of of penalty matrices. <code>S[[i]]</code> is the <i>i</i> th penalty matrix, but note that it is not stored as a full matrix, but rather as the smallest square matrix including all the non-zero elements of the penalty matrix. Element 1,1 of <code>S[[i]]</code> occupies element <code>off[i], off[i]</code> of the <i>i</i> th penalty matrix. Each <code>S[[i]]</code> must be positive semi-definite. Set to <code>list()</code> if there are no smoothing parameters to be estimated.
<code>off</code>	is an array indicating the first parameter in the parameter vector that is penalized by the penalty involving <code>S[[i]]</code> .
<code>L</code>	is a matrix mapping <code>log(sp)</code> to the log smoothing parameters that actually multiply the penalties defined by the elems of <code>S</code> . Taken as the identity, if <code>NULL</code> . See above under <code>sp</code> .
<code>lsp0</code>	If <code>L</code> is not <code>NULL</code> this is a vector of constants in the linear transformation from <code>log(sp)</code> to the actual log smoothing parameters. So the logs of the smoothing parameters multiplying the <code>S[[i]]</code> are given by <code>L%%log(sp) + lsp0</code> . Taken as 0 if <code>NULL</code> .
<code>rank</code>	is an array specifying the ranks of the penalties. This is useful, but not essential, for forming square roots of the penalty matrices.
<code>H</code>	is the optional offset penalty - i.e. a penalty with a smoothing parameter fixed at 1. This is useful for allowing regularization of the estimation process, fixed smoothing penalties etc.
<code>C</code>	is the optional matrix specifying any linear equality constraints on the fitting problem. If <code>b</code> is the parameter vector then the parameters are forced to satisfy $Cb = 0$ .
<code>w</code>	the regression weights. If this is a matrix then it is taken as being the square root of the inverse of the covariance matrix of <code>y</code> , specifically $V_y^{-1} = w'w$ . If <code>w</code> is an array then it is taken as the diagonal of this matrix, or simply the weight for each element of <code>y</code> . See below for an example using this.
<code>gamma</code>	is an inflation factor for the model degrees of freedom in the GCV or UBRE score.
<code>scale</code>	is the scale parameter for use with UBRE.
<code>gcv</code>	should be set to <code>TRUE</code> if GCV is to be used, <code>FALSE</code> for UBRE.
<code>ridge.parameter</code>	It is sometimes useful to apply a ridge penalty to the fitting problem, penalizing the parameters in the constrained space directly. Setting this parameter to a value greater than zero will cause such a penalty to be used, with the magnitude given by the parameter value.
<code>control</code>	is a list of iteration control constants with the following elements: <b>tol</b> The tolerance to use in judging convergence. <b>step.half</b> If a trial step fails then the method tries halving it up to a maximum of <code>step.half</code> times. <b>rank.tol</b> is a constant used to test for numerical rank deficiency of the problem. Basically any singular value less than <code>rank_tol</code> multiplied by the largest singular value of the problem is set to zero.
<code>extra.rss</code>	is a constant to be added to the residual sum of squares (squared norm) term in the calculation of the GCV, UBRE and scale parameter estimate. In conjunction with <code>n.score</code> , this is useful for certain methods for dealing with very large data sets.

<code>n.score</code>	number to use as the number of data in GCV/UBRE score calculation: usually the actual number of data, but there are methods for dealing with very large datasets that change this.
<code>nthreads</code>	<code>magic</code> can make use of multiple threads if this is set to $>1$ .

## Details

The method is a computationally efficient means of applying GCV or UBRE (often approximately AIC) to the problem of smoothing parameter selection in generalized ridge regression problems of the form:

$$\text{minimise } \|\mathbf{W}(\mathbf{X}\mathbf{b} - \mathbf{y})\|^2 + \mathbf{b}'\mathbf{H}\mathbf{b} + \sum_{i=1}^m \theta_i \mathbf{b}'\mathbf{S}_i\mathbf{b}$$

possibly subject to constraints  $\mathbf{C}\mathbf{b} = \mathbf{0}$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{b}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty with associated smoothing parameter  $\theta_i$ ,  $\mathbf{H}$  is the positive semi-definite offset penalty matrix and  $\mathbf{C}$  a matrix of coefficients defining any linear equality constraints on the problem.  $\mathbf{X}$  need not be of full column rank.

The  $\theta_i$  are chosen to minimize either the GCV score:

$$V_g = \frac{n\|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2}{[tr(\mathbf{I} - \gamma\mathbf{A})]^2}$$

or the UBRE score:

$$V_u = \|\mathbf{W}(\mathbf{y} - \mathbf{A}\mathbf{y})\|^2/n - 2\phi tr(\mathbf{I} - \gamma\mathbf{A})/n + \phi$$

where  $\gamma$  is gamma the inflation factor for degrees of freedom (usually set to 1) and  $\phi$  is scale, the scale parameter.  $\mathbf{A}$  is the hat matrix (influence matrix) for the fitting problem (i.e the matrix mapping data to fitted values). Dependence of the scores on the smoothing parameters is through  $\mathbf{A}$ .

The method operates by Newton or steepest descent updates of the logs of the  $\theta_i$ . A key aspect of the method is stable and economical calculation of the first and second derivatives of the scores w.r.t. the log smoothing parameters. Because the GCV/UBRE scores are flat w.r.t. very large or very small  $\theta_i$ , it's important to get good starting parameters, and to be careful not to step into a flat region of the smoothing parameter space. For this reason the algorithm rescales any Newton step that would result in a  $\log(\theta_i)$  change of more than 5. Newton steps are only used if the Hessian of the GCV/UBRE is positive definite, otherwise steepest descent is used. Similarly steepest descent is used if the Newton step has to be contracted too far (indicating that the quadratic model underlying Newton is poor). All initial steepest descent steps are scaled so that their largest component is 1. However a step is calculated, it is never expanded if it is successful (to avoid flat portions of the objective), but steps are successively halved if they do not decrease the GCV/UBRE score, until they do, or the direction is deemed to have failed. (Given the smoothing parameters the optimal  $\mathbf{b}$  parameters are easily found.)

The method is coded in C with matrix factorizations performed using LINPACK and LAPACK routines.

## Value

The function returns a list with the following items:

<code>b</code>	The best fit parameters given the estimated smoothing parameters.
----------------	---

<code>scale</code>	the estimated (GCV) or supplied (UBRE) scale parameter.
<code>score</code>	the minimized GCV or UBRE score.
<code>sp</code>	an array of the estimated smoothing parameters.
<code>sp.full</code>	an array of the smoothing parameters that actually multiply the elements of $S$ (same as <code>sp</code> if <code>L</code> was <code>NULL</code> ). This is <code>exp(L%%log(sp))</code> .
<code>rV</code>	a factored form of the parameter covariance matrix. The (Bayesian) covariance matrix of the parameters <code>b</code> is given by <code>rV%%t(rV)*scale</code> .
<code>gcv.info</code>	is a list of information about the performance of the method with the following elements: <b>full.rank</b> The apparent rank of the problem: number of parameters less number of equality constraints. <b>rank</b> The estimated actual rank of the problem (at the final iteration of the method). <b>fully.converged</b> is <code>TRUE</code> if the method converged by satisfying the convergence criteria, and <code>FALSE</code> if it covered by failing to decrease the score along the search direction. <b>hess.pos.def</b> is <code>TRUE</code> if the hessian of the UBRE or GCV score was positive definite at convergence. <b>iter</b> is the number of Newton/Steepest descent iterations taken. <b>score.calls</b> is the number of times that the GCV/UBRE score had to be evaluated. <b>rms.grad</b> is the root mean square of the gradient of the UBRE/GCV score w.r.t. the smoothing parameters. <b>R</b> The factor <code>R</code> from the QR decomposition of the weighted model matrix. This is un-pivoted so that column order corresponds to <code>X</code> . So it may not be upper triangular.

Note that some further useful quantities can be obtained using `magic.post.proc`.

```

---

magic.post.proc      *Auxilliary information from magic fit*

---

## Description

Obtains Bayesian parameter covariance matrix, frequentist parameter estimator covariance matrix, estimated degrees of freedom for each parameter and leading diagonal of influence/hat matrix, for

a penalized regression estimated by `magic`.

### Usage

```
magic.post.proc(X, object, w=NULL)
```

### Arguments

<code>X</code>	is the model matrix.
<code>object</code>	is the list returned by <code>magic</code> after fitting the model with model matrix <code>X</code> .
<code>w</code>	is the weight vector used in fitting, or the weight matrix used in fitting (i.e. supplied to <code>magic</code> , if one was.). If <code>w</code> is a vector then its elements are typically proportional to reciprocal variances (but could even be negative). If <code>w</code> is a matrix then <code>t(w) %*% w</code> should typically give the inverse of the covariance matrix of the response data supplied to <code>magic</code> .

### Details

`object` contains `rV(V, say)`, and `scale(phi, say)` which can be used to obtain the require quantities as follows. The Bayesian covariance matrix of the parameters is  $\mathbf{V}\mathbf{V}'\phi$ . The vector of estimated degrees of freedom for each parameter is the leading diagonal of  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}$  where  $\mathbf{W}$  is either the weight matrix `w` or the matrix `diag(w)`. The hat/influence matrix is given by  $\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'$ .

The frequentist parameter estimator covariance matrix is  $\mathbf{V}\mathbf{V}'\mathbf{X}'\mathbf{W}'\mathbf{W}\mathbf{X}\mathbf{V}\mathbf{V}'\phi$ : it is sometimes useful for testing terms for equality to zero.

### Value

A list with three items:

<code>Vb</code>	the Bayesian covariance matrix of the model parameters.
<code>Ve</code>	the frequentist covariance matrix for the parameter estimators.
<code>hat</code>	the leading diagonal of the hat (influence) matrix.
<code>edf</code>	the array giving the estimated degrees of freedom associated with each parameter.

## Description

This page provides answers to some of the questions that get asked most often about mgcv

## FAQ list

1. **How can I compare gamm models?** In the identity link normal errors case, then AIC and hypothesis testing based methods are fine. Otherwise it is best to work out a strategy based on the [summary.gam](#). Alternatively, simple random effects can be fitted with [gam](#), which makes comparison straightforward. Package [gamm4](#) is an alternative, which allows AIC type model selection for generalized models.
2. **How do I get the equation of an estimated smooth?** This slightly misses the point of semi-parametric modelling: the idea is that we estimate the form of the function from data without assuming that it has a particular simple functional form. Of course for practical computation the functions do have underlying mathematical representations, but they are not very helpful, when written down. If you do need the functional forms then see chapter 4 of Wood (2006). However for most purposes it is better to use [predict.gam](#) to evaluate the function for whatever argument values you need. If derivatives are required then the simplest approach is to use finite differencing (which also allows SEs etc to be calculated).
3. **Some of my smooths are estimated to be straight lines and their confidence intervals vanish at some point in the middle. What is wrong?** Nothing. Smooths are subject to sum-to-zero identifiability constraints. If a smooth is estimated to be a straight line then it consequently has one degree of freedom, and there is no choice about where it passes through zero — so the CI must vanish at that point.
4. **How do I test whether a smooth is significantly different from a straight line.** See [tprs](#) and the example therein.
5. **Some code from Wood (2006) causes an error: why?** The book was written using mgcv version 1.3. To allow for REML estimation of smoothing parameters in versions 1.5, some changes had to be made to the syntax. In particular the function `gam.method` no longer exists. The smoothness selection method (GCV, REML etc) is now controlled by the `method` argument to `gam` while the optimizer is selected using the `optimizer` argument. See [gam](#) and <http://www.maths.bath.ac.uk/~sw283/igam/index.html> for details.
6. **Why is a model object saved under a previous mgcv version not usable with the current mgcv version?** I'm sorry about this issue, I know it's really annoying. Here's my defence. Each mgcv version is run through an extensive test suite before release, to ensure that it gives the same results as before, unless there are good statistical reasons why not (e.g. improvements to p-value approximation, fixing of an error). However it is sometimes necessary to modify the internal structure of model objects in a way that makes an old style object unusable with a newer version. For example, bug fixes or new R features sometimes require changes in the way that things are computed which in turn require modification of the object structure. Similarly improvements, such as the ability to compute smoothing parameters by RE/ML require object level changes. The only fix to this problem is to access the old object using the original mgcv version (available on CRAN), or to recompute the fit using the current mgcv version.
7. **When using gamm or gamm4, the reported AIC is different for the gam object and the lme or lmer object. Why is this?** There are several reasons for this. The most important is that the models being used are actually different in the two representations. When treating the

GAM as a mixed model, you are implicitly assuming that if you gathered a replicate dataset, the smooths in your model would look completely different to the smooths from the original model, except for having the same degree of smoothness. Technically you would expect the smooths to be drawn afresh from their distribution under the random effects model. When viewing the gam from the usual penalized regression perspective, you would expect smooths to look broadly similar under replication of the data. i.e. you are really using Bayesian model for the smooths, rather than a random effects model (it's just that the frequentist random effects and Bayesian computations happen to coincide for computing the estimates). As a result of the different assumptions about the data generating process, AIC model comparisons can give rather different answers depending on the model adopted. Which you use should depend on which model you really think is appropriate. In addition the computations of the AICs are different. The mixed model AIC uses the marginal likelihood and the corresponding number of model parameters. The gam model uses the penalized likelihood and the effective degrees of freedom.

8. **What does 'mgcv' stand for?** 'Mixed GAM Computation Vehicle', is my current best effort (let me know if you can do better). Originally it stood for 'Multiple GCV', which has long since ceased to be usefully descriptive, (and I can't really change 'mgcv' now without causing disruption). On a bad inbox day 'Mad GAM Computing Vulture'.
9. **My new method is failing to beat mgcv, what can I do?** If speed is the problem, then make sure that you use the slowest basis possible ("`tp`") with a large sample size, and experiment with different optimizers to find one that is slow for your problem. For prediction error/MSE, then leaving the smoothing basis dimensions at their arbitrary defaults, when these are inappropriate for the problem setting, is a good way of reducing performance. Similarly, using p-splines in place of derivative penalty based splines will often shave a little more from the performance here. Unlike REML/ML, prediction error based smoothness selection criteria such as Mallows Cp and GCV often produce a small proportion of severe overfits, so careful choice of smoothness selection method can help further. In particular GCV etc. usually result in worse confidence interval and p-value performance than ML or REML. If all this fails, try using a really odd simulation setup for which mgcv is clearly not suited: for example poor performance is almost guaranteed for small noisy datasets with large numbers of predictors.

mgcv.package

*Mixed GAM Computation Vehicle with GCV/AIC/REML smoothness estimation and GAMMs by REML/PQL*

---

#### Description

mgcv provides functions for generalized additive modelling ([gam](#) and [bam](#)) and generalized additive mixed modelling ([gamm](#), and [random.effects](#)). The term GAM is taken to include any model dependent on unknown smooth functions of predictors and estimated by quadratically penalized (possibly quasi-) likelihood maximization. Available distributions are covered in [family.mgcv](#) and available smooths in [smooth.terms](#).

Particular features of the package are facilities for automatic smoothness selection (Wood, 2004, 2011), and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also available.

## Details

`mgcv` provides generalized additive modelling functions `gam`, `predict.gam` and `plot.gam`, which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other functions such as `summary.gam` and `anova.gam` are also provided, for extracting information from a fitted `gamObject`.

Use of `gam` is much like use of `glm`, except that within a `gam` model formula, isotropic smooths of any number of predictors can be specified using `s` terms, while scale invariant smooths of any number of predictors can be specified using `te`, `ti` or `t2` terms. `smooth.terms` provides an overview of the built in smooth classes, and `random.effects` should be referred to for an overview of random effects terms (see also `mrf` for Markov random fields). Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV, GACV, gAIC/UBRE or (RE)ML. See `gam`, `gam.models`, `linear.functional.terms` and `gam.selection` for some discussion of model specification and selection. For detailed control of fitting see `gam.convergence`, `gam` arguments `method` and `optimizer` and `gam.control`. For checking and visualization see `gam.check`, `choose.k`, `vis.gam` and `plot.gam`. While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see `smooth.construct`, for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals (see Marra and Wood, 2012). The Bayesian covariance matrix for the model coefficients is returned in `Vp` of the `gamObject`. See `predict.gam` for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas (see Wood, 2013a,b). Frequentist approximations can be used for hypothesis testing based model comparison. See `anova.gam` and `summary.gam` for more on hypothesis testing.

For large datasets (that is large `n`) see `bam` which is a version of `gam` with a much reduced memory footprint.

The package also provides a generalized additive mixed modelling function, `gamm`, based on a PQL approach and `lme` from the `nlme` library (for an `lme4` based version, see package `gamm4`). `gamm` is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine `magic` can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see `magic`. But there is little functionality that can not be more conveniently accessed via `gam`. Penalized weighted least squares with linear equality and inequality constraints is provided by `pcls`.

For a complete list of functions type `library(help=mgcv)`. See also `mgcv.FAQ`.

mgcv.parallel	<i>Parallel computation in mgcv.</i>
---------------	--------------------------------------

---

## Description

mgcv can make some use of multiple cores or a cluster. Function [bam](#) uses the facilities provided in the [parallel](#) package for this purpose. See examples below. Note that most multi-core machines are memory bandwidth limited, so parallel speed up tends to be rather variable.

[bam](#) can also use an alternative openMP based parallelization approach alongside discretisation of covariates to achieve substantial speed ups. This is selected using the `discrete=TRUE` option to [bam](#), with the number of threads controlled via the `nthreads` argument. See example below.

Function [gam](#) can use parallel threads on a (shared memory) multi-core machine via openMP (where this is supported). To do this, set the desired number of threads by setting `nthreads` to the number of cores to use, in the `control` argument of [gam](#). Note that, for the most part, only the dominant  $O(np^2)$  steps are parallelized (n is number of data, p number of parameters). For additive Gaussian models estimated by GCV, the speed up can be disappointing as these employ an  $O(p^3)$  SVD step that can also have substantial cost in practice.

[magic](#) can also use multiple cores, but the same comments apply as for the GCV Gaussian additive model.

If `control$nthreads` is set to more than the number of cores detected, then only the number of detected cores is used. Note that using virtual cores usually gives very little speed up, and can even slow computations slightly. For example, many Intel processors reporting 4 cores actually have 2 physical cores, each with 2 virtual cores, so using 2 threads gives a marked increase in speed, while using 4 threads makes little extra difference.

Note that on Intel and similar processors the maximum performance is usually achieved by disabling Hyper-Threading in BIOS, and then setting the number of threads to the number of physical cores used. This prevents the operating system scheduler from sending 2 floating point intensive threads to the same physical core, where they have to share a floating point unit (and cache) and therefore slow each other down. The scheduler tends to do this under the manager - worker multi-threading approach used in mgcv, since the manager thread looks very busy up to the point at which the workers are set to work, and at the point of scheduling the scheduler has no way of knowing that the manager thread actually has nothing more to do until the workers are finished. If you are working on a many cored platform where you can not disable hyper-threading then it may be worth setting the number of threads to one less than the number of physical cores, to reduce the frequency of such scheduling problems.

mgcv's work splitting always makes the simple assumption that all your cores are equal, and you are not sharing them with other floating point intensive threads.

In addition to hyper-threading several features may lead to apparently poor scaling. The first is that many CPUs have a Turbo mode, whereby a few cores can be run at higher frequency, provided the overall power used by the CPU does not exceed design limits, however it is not possible for all cores on the CPU to run at this frequency. So as you add threads eventually the CPU frequency has to be reduced below the Turbo frequency, with the result that you don't get the expected speed up from adding cores. Secondly, most modern CPUs have their frequency set dynamically according to load. You may need to set the system power management policy to favour high performance in order to maximize the chance that all threads run at the speed you were hoping for (you can turn off dynamic power control in BIOS, but then you turn off the possibility of Turbo also).

Because the computational burden in mgcv is all in the linear algebra, then parallel computation may provide reduced or no benefit with a tuned BLAS. This is particularly the case if you are using a multi threaded BLAS, but a BLAS that is tuned to make efficient use of a particular cache size may also experience loss of performance if threads have to share the cache.

model.matrix.gam	<i>Extract model matrix from GAM fit</i>
------------------	--

---

## Description

Obtains the model matrix from a fitted gam object.

## Usage

```
## S3 method for class 'gam'
model.matrix(object, ...)
```

## Arguments

object	fitted model object of class gam as produced by gam().
...	other arguments, passed to <a href="#">predict.gam</a> .

## Details

Calls [predict.gam](#) with no newdata argument and type="lpmatrix" in order to obtain the model matrix of object.

**Value**

A model matrix.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

Wood S.N. (2006b) Generalized Additive Models: An Introduction with R. Chapman and Hall/CRC Press.

**See Also**

**Examples**

```
require(mgcv)
n <- 15
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=6),knots=list(x=seq(0,1,length=6)))
model.matrix(mod)
```

---

mono.con

*Monotonicity constraints for a cubic regression spline*

---

**Description**

Finds linear constraints sufficient for monotonicity (and optionally upper and/or lower boundedness) of a cubic regression spline. The basis representation assumed is that given by the `gam`, "cr" basis: that is the spline has a set of knots, which have fixed x values, but the y values of which constitute the parameters of the spline.

**Usage**

```
mono.con(x, up=TRUE, lower=NA, upper=NA)
```

**Arguments**

<code>x</code>	The array of knot locations.
<code>up</code>	If <code>TRUE</code> then the constraints imply increase, if <code>FALSE</code> then decrease.
<code>lower</code>	This specifies the lower bound on the spline unless it is <code>NA</code> in which case no lower bound is imposed.
<code>upper</code>	This specifies the upper bound on the spline unless it is <code>NA</code> in which case no upper bound is imposed.

## Details

Consider the natural cubic spline passing through the points  $\{x_i, p_i : i = 1 \dots n\}$ . Then it is possible to find a relatively small set of linear constraints on  $\mathbf{p}$  sufficient to ensure monotonicity (and bounds if required):  $\mathbf{A}\mathbf{p} \geq \mathbf{b}$ . Details are given in Wood (1994).

## Value

a list containing constraint matrix A and constraint vector b.

mroot

*Smallest square root of matrix*

---

## Description

Find a square root of a positive semi-definite matrix, having as few columns as possible. Uses either pivoted choleski decomposition or singular value decomposition to do this.

## Usage

```
mroot(A, rank=NULL, method="chol")
```

## Arguments

A	The positive semi-definite matrix, a square root of which is to be found.
rank	if the rank of the matrix A is known then it should be supplied. NULL or <1 imply that it should be estimated.
method	"chol" to use pivoted choleski decomposition, which is fast but tends to over-estimate rank. "svd" to use singular value decomposition, which is slow, but is the most accurate way to estimate rank.

## Details

The function uses SVD, or a pivoted Choleski routine. It is primarily of use for turning penalized regression problems into ordinary regression problems.

## Value

A matrix, **B** with as many columns as the rank of **A**, and such that  $\mathbf{A} = \mathbf{B}\mathbf{B}'$ .

## Author(s)

Simon N. Wood <simon.wood@r-project.org>

## Examples

```
require(mgcv)
set.seed(0)
a <- matrix(runif(24), 6, 4)
A <- a%*%t(a) ## A is +ve semi-definite, rank 4
B <- mroot(A) ## default pivoted choleski method
tol <- 100*.Machine$double.eps
chol.err <- max(abs(A-B%*%t(B)));chol.err
if (chol.err>tol) warning("mroot (chol) suspect")
B <- mroot(A,method="svd") ## svd method
svd.err <- max(abs(A-B%*%t(B)));svd.err
if (svd.err>tol) warning("mroot (svd) suspect")
```

---

mvn

---

*Multivariate normal additive models*

---

## Description

Family for use with [gam](#) implementing smooth multivariate Gaussian regression. The means for each dimension are given by a separate linear predictor, which may contain smooth components. The Choleski factor of the response precision matrix is estimated as part of fitting.

## Usage

```
mvn(d=2)
```

## Arguments

d                      The dimension of the response (>1).

## Details

The response is *d* dimensional multivariate normal, where the covariance matrix is estimated, and the means for each dimension have sperate linear predictors. Model sepcification is via a list of gam like formulae - one for each dimension. See example.

Currently the family ignores any prior weights, and is implemented using first derivative information sufficient for BFGS estimation of smoothing parameters. "response" residuals give raw residuals, while "deviance" residuals are standardized to be approximately independent standard normal if all is well.

**Value**

An object of class `general.family`.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

```

---

negbin

*GAM negative binomial families*

---

**Description**

The `gam` modelling function is designed to be able to use the [negbin](#) family (a modification of MASS library `negative.binomial` family by Venables and Ripley), or the [nb](#) function designed for integrated estimation of parameter `theta`.  $\theta$  is the parameter such that  $\text{var}(y) = \mu + \mu^2/\theta$ , where  $\mu = E(y)$ .

Two approaches to estimating `theta` are available (with [gam](#) only):

- With `negbin` then if ‘performance iteration’ is used for smoothing parameter estimation (see [gam](#)), then smoothing parameters are chosen by GCV and `theta` is chosen in order to ensure that the Pearson estimate of the scale parameter is as close as possible to 1, the value that the scale parameter should have.

- If ‘outer iteration’ is used for smoothing parameter selection with the `nb` family then `theta` is estimated alongside the smoothing parameters by ML or REML.

To use the first option, set the `optimizer` argument of `gam` to `"perf"` (it can sometimes fail to converge).

## Usage

```
negbin(theta = stop("'theta' must be specified"), link = "log")
nb(theta = NULL, link = "log")
```

## Arguments

<code>theta</code>	Either i) a single value known value of <code>theta</code> or ii) two values of <code>theta</code> specifying the endpoints of an interval over which to search for <code>theta</code> (this is an option only for <code>negbin</code> ). For <code>nb</code> then a positive supplied <code>theta</code> is treated as a fixed known parameter, otherwise it is estimated (the absolute value of a negative <code>theta</code> is taken as a starting value).
<code>link</code>	The link function: one of <code>"log"</code> , <code>"identity"</code> or <code>"sqrt"</code>

## Details

`nb` allows estimation of the `theta` parameter alongside the model smoothing parameters, but is only useable with `gam` (not `bam` or `gamm`).

For `negbin`, if a single value of `theta` is supplied then it is always taken as the known fixed value and this is useable with `bam` and `gamm`. If `theta` is two numbers (`theta[2] > theta[1]`) then they are taken as specifying the range of values over which to search for the optimal `theta`. This option should only be used with performance iteration estimation (see `gam` argument `optimizer`), in which case the method of estimation is to choose  $\hat{\theta}$  so that the GCV (Pearson) estimate of the scale parameter is one (since the scale parameter is one for the negative binomial). In this case  $\theta$  estimation is nested within the IRLS loop used for GAM fitting. After each call to fit an iteratively weighted additive model to the IRLS pseudodata, the  $\theta$  estimate is updated. This is done by conditioning on all components of the current GCV/Pearson estimator of the scale parameter except  $\theta$  and then searching for the  $\hat{\theta}$  which equates this conditional estimator to one. The search is a simple bisection search after an initial crude line search to bracket one. The search will terminate at the upper boundary of the search region is a Poisson fit would have yielded an estimated scale parameter  $< 1$ .

The following `negbin` based approaches are now deprecated:

If outer iteration is used then  $\theta$  is estimated by searching for the value yielding the lowest AIC. The search is either over the supplied array of values, or is a grid search over the supplied range, followed by a golden section search. A full fit is required for each trial  $\theta$ , so the process is slow, but speed is enhanced by making the changes in  $\theta$  as small as possible, from one step to the next, and using the previous smothing parameter and fitted values to start the new fit.

In a simulation test based on 800 replicates of the first example data, given below, the GCV based (performance iteration) method yielded models with, on average 6% better MSE performance than the AIC based (outer iteration) method. `theta` had a 0.86 correlation coefficient between the two methods. `theta` estimates averaged 3.36 with a standard deviation of 0.44 for the AIC based method and 3.22 with a standard deviation of 0.43 for the GCV based method. However the GCV based method is less computationally reliable, failing in around 4% of replicates.

**Value**

For `negbin` an object inheriting from class `family`, with additional elements

<code>dvar</code>	the function giving the first derivative of the variance function w.r.t. <code>mu</code> .
<code>d2var</code>	the function giving the second derivative of the variance function w.r.t. <code>mu</code> .
<code>getTheta</code>	A function for retrieving the value(s) of <code>theta</code> . This also useful for retrieving the estimate of <code>theta</code> after fitting (see example).

For `nb` an object inheriting from class `extended.family`.

**WARNINGS**

`gamm` and `bam` do not support `theta` estimation

The negative binomial functions from the MASS library are no longer supported.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org> modified from Venables and Ripley's `negative.binomial` family.

**References**

**Examples**

```
library(mgcv)
set.seed(3)
n<-400
dat <- gamSim(1,n=n)
g <- exp(dat$f/5)

## negative binomial data...
dat$y <- rnbinom(g,size=3,mu=g)
## known theta fit ...
b0 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(3),data=dat)
plot(b0,pages=1)
print(b0)

## same with theta estimation...
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=nb(),data=dat)
plot(b,pages=1)
print(b)
b$family$getTheta(TRUE) ## extract final theta estimate

## unknown theta via performance iteration...
b1 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=negbin(c(1,10)),
          optimizer="perf",data=dat)
plot(b1,pages=1)
print(b1)

## another example...
set.seed(1)
f <- dat$f
f <- f - min(f)+5;g <- f^2/10
```

```
dat$y <- rnbinom(g, size=3, mu=g)
b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=nb(link="sqrt"),
          data=dat, method="REML")
plot(b2, pages=1)
print(b2)
rm(dat)
```

---

`new.name`*Obtain a name for a new variable that is not already in use*

---

## Description

`gamm` works by transforming a GAMM into something that can be estimated by `lme`, but this involves creating new variables, the names of which should not clash with the names of other variables on which the model depends. This simple service routine checks a suggested name against a list of those in use, and if necessary modifies it so that there is no clash.

## Usage

```
new.name(proposed, old.names)
```

## Arguments

<code>proposed</code>	a suggested name
<code>old.names</code>	An array of names that must not be duplicated

## Value

A name that is not in `old.names`.

## Author(s)

---

notExp*Functions for better-than-log positive parameterization*

---

## Description

It is common practice in statistical optimization to use log-parameterizations when a parameter ought to be positive. i.e. if an optimization parameter  $a$  should be non-negative then we use  $a = \exp(b)$  and optimize with respect to the unconstrained parameter  $b$ . This often works well, but it does imply a rather limited working range for  $b$ : using 8 byte doubles, for example, if  $b$ 's magnitude gets much above 700 then  $a$  overflows or underflows. This can cause problems for numerical optimization methods.

`notExp` is a monotonic function for mapping the real line into the positive real line with much less extreme underflow and overflow behaviour than `exp`. It is a piece-wise function, but is continuous to second derivative: see the source code for the exact definition, and the example below to see what it looks like.

`notLog` is the inverse function of `notExp`.

The major use of these functions was originally to provide more robust `pdMat` classes for `lme` for use by `gamm`. Currently the `notExp2` and `notLog2` functions are used in their place, as a result of changes to the nlme optimization routines.

## Usage

```
notExp(x)
```

```
notLog(x)
```

## Arguments

`x`                      Argument array of real numbers (`notExp`) or positive real numbers (`notLog`).

## Value

An array of function values evaluated at the supplied argument values.

## Author(s)

## Examples

```
## Illustrate the notExp function:
## less steep than exp, but still monotonic.
require(mgcv)
x <- -100:100/10
op <- par(mfrow=c(2,2))
plot(x, notExp(x), type="l")
lines(x, exp(x), col=2)
plot(x, log(notExp(x)), type="l")
lines(x, log(exp(x)), col=2) # redundancy intended
x <- x/4
plot(x, notExp(x), type="l")
lines(x, exp(x), col=2)
plot(x, log(notExp(x)), type="l")
lines(x, log(exp(x)), col=2) # redundancy intended
par(op)
range(notLog(notExp(x))-x) # show that inverse works!
```

notExp2

*Alternative to log parameterization for variance components*

## Description

notLog2 and notExp2 are alternatives to log and exp or [notLog](#) and [notExp](#) for reparameterization of variance parameters. They are used by the [pdTens](#) and [pdIdnot](#) classes which in turn implement smooths for [gamm](#).

The functions are typically used to ensure that smoothing parameters are positive, but the notExp2 is not monotonic: rather it cycles between ‘effective zero’ and ‘effective infinity’ as its argument changes. The notLog2 is the inverse function of the notExp2 only over an interval centered on zero.

Parameterizations using these functions ensure that estimated smoothing parameters remain positive, but also help to ensure that the likelihood is never indefinite: once a working parameter pushes a smoothing parameter below ‘effective zero’ or above ‘effective infinity’ the cyclic nature of the notExp2 causes the likelihood to decrease, where otherwise it might simply have flattened.

This parameterization is really just a numerical trick, in order to get lme to fit gamm models, without failing due to indefiniteness. Note in particular that asymptotic results on the likelihood/REML criterion are not invalidated by the trick, unless parameter estimates end up close to the effective zero or effective infinity: but if this is the case then the asymptotics would also have been invalid for a conventional monotonic parameterization.

This reparameterization was made necessary by some modifications to the underlying optimization method in lme introduced in nlme 3.1-62. It is possible that future releases will return to the [notExp](#) parameterization.

Note that you can reset ‘effective zero’ and ‘effective infinity’: see below.

## Usage

```
notExp2(x, d=Options$mgcv.vc.logrange, b=1/d)
```

```
notLog2(x, d=Options$mgcv.vc.logrange, b=1/d)
```

**Arguments**

<code>x</code>	Argument array of real numbers ( <code>notExp</code> ) or positive real numbers ( <code>notLog</code> ).
<code>d</code>	the range of <code>notExp2</code> runs from $\exp(-d)$ to $\exp(d)$ . To change the range used by <code>gamm</code> reset <code>mgcv.vc.logrange</code> using <a href="#">options</a> .
<code>b</code>	determines the period of the cycle of <code>notExp2</code> .

**Value**

An array of function values evaluated at the supplied argument values.

---

null.space.dimension

*The basis of the space of un-penalized functions for a TPRS*

---

**Description**

The thin plate spline penalties give zero penalty to some functions. The space of these functions is spanned by a set of polynomial terms. `null.space.dimension` finds the dimension of this space,  $M$ , given the number of covariates that the smoother is a function of,  $d$ , and the order of the smoothing penalty,  $m$ . If  $m$  does not satisfy  $2m > d$  then the smallest possible dimension for the null space is found given  $d$  and the requirement that the smooth should be visually smooth.

**Usage**

```
null.space.dimension(d,m)
```

**Arguments**

`d` is a positive integer - the number of variables of which the t.p.s. is a function.  
`m` a non-negative integer giving the order of the penalty functional, or signalling that the default order should be used.

**Details**

Thin plate splines are only visually smooth if the order of the wiggleness penalty,  $m$ , satisfies  $2m > d + 1$ . If  $2m < d + 1$  then this routine finds the smallest  $m$  giving visual smoothness for the given  $d$ , otherwise the supplied  $m$  is used. The null space dimension is given by:

$$M = (m + d - 1)! / (d!(m - 1)!)$$

which is the value returned.

**Value**

An integer (array), the null space dimension  $M$ .

**Author(s)**

---

**Description**

Family for use with [gam](#), implementing regression for ordered categorical data. A linear predictor provides the expected value of a latent variable following a logistic distribution. The probability of this latent variable lying between certain cut-points provides the probability of the ordered categorical variable being of the corresponding category. The cut-points are estimated along side the model smoothing parameters (using the same criterion). The observed categories are coded 1, 2, 3, ... up to the number of categories.

**Usage**

```
ocat(theta=NULL, link="identity", R=NULL)
```

**Arguments**

<code>theta</code>	cut point parameter vector (dimension $R-2$ ). If supplied and all positive, then taken to be the cut point increments (first cut point is fixed at -1). If any are negative then absolute values are taken as starting values for cutpoint increments.
<code>link</code>	The link function: only "identity" allowed at present (possibly for ever).
<code>R</code>	the number of categories.

**Details**

Such cumulative threshold models are only identifiable up to an intercept, or one of the cut points. Rather than remove the intercept, `ocat` simply sets the first cut point to -1. Use `predict.gam` with `type="response"` to get the predicted probabilities in each category.

**Value**

An object of class `extended.family`.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```
library(mgcv)
## Simulate some ordered categorical data...
set.seed(3); n<-400
dat <- gamSim(1, n=n)
dat$f <- dat$f - mean(dat$f)

alpha <- c(-Inf, -1, 0, 5, Inf)
R <- length(alpha)-1
y <- dat$f
u <- runif(n)
u <- dat$f + log(u/(1-u))
for (i in 1:R) {
  y[u > alpha[i]&u <= alpha[i+1]] <- i
}
dat$y <- y

## plot the data...
par(mfrow=c(2,2))
with(dat, plot(x0, y)); with(dat, plot(x1, y))
with(dat, plot(x2, y)); with(dat, plot(x3, y))

## fit ocat model to data...
b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=ocat(R=R), data=dat)
b
plot(b, pages=1)
gam.check(b)
summary(b)
b$family$getTheta(TRUE) ## the estimated cut points
```

```
## predict probabilities of being in each category
predict(b, dat[1:2, ], type="response", se=TRUE)
```

pcls

*Penalized Constrained Least Squares Fitting*

## Description

Solves least squares problems with quadratic penalties subject to linear equality and inequality constraints using quadratic programming.

## Usage

```
pcls(M)
```

## Arguments

- M** is the single list argument to `pcls`. It should have the following elements:
- y** The response data vector.
  - w** A vector of weights for the data (often proportional to the reciprocal of the variance).
  - X** The design matrix for the problem, note that `ncol(M$X)` must give the number of model parameters, while `nrow(M$X)` should give the number of data.
  - C** Matrix containing any linear equality constraints on the problem (e.g.  $\mathbf{Cp} = \mathbf{c}$ ). If you have no equality constraints initialize this to a zero by zero matrix. Note that there is no need to supply the vector  $\mathbf{c}$ , it is defined implicitly by the initial parameter estimates  $\mathbf{p}$ .
  - S** A list of penalty matrices.  $S[[i]]$  is the smallest contiguous matrix including all the non-zero elements of the  $i$ th penalty matrix. The first parameter it penalizes is given by `off[i]+1` (starting counting at 1).
  - off** Offset values locating the elements of  $M\$S$  in the correct location within each penalty coefficient matrix. (Zero offset implies starting in first location)
  - sp** An array of smoothing parameter estimates.
  - p** An array of feasible initial parameter estimates - these must satisfy the constraints, but should avoid satisfying the inequality constraints as equality constraints.
  - Ain** Matrix for the inequality constraints  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ .
  - bin** vector in the inequality constraints.

## Details

This solves the problem:

$$\text{minimise } \|\mathbf{W}^{1/2}(\mathbf{Xp} - \mathbf{y})\|^2 + \sum_{i=1}^m \lambda_i \mathbf{p}' \mathbf{S}_i \mathbf{p}$$

subject to constraints  $\mathbf{C}\mathbf{p} = \mathbf{c}$  and  $\mathbf{A}_{in}\mathbf{p} > \mathbf{b}_{in}$ , w.r.t.  $\mathbf{p}$  given the smoothing parameters  $\lambda_i$ .  $\mathbf{X}$  is a design matrix,  $\mathbf{p}$  a parameter vector,  $\mathbf{y}$  a data vector,  $\mathbf{W}$  a diagonal weight matrix,  $\mathbf{S}_i$  a positive semi-definite matrix of coefficients defining the  $i$ th penalty and  $\mathbf{C}$  a matrix of coefficients defining the linear equality constraints on the problem. The smoothing parameters are the  $\lambda_i$ . Note that  $\mathbf{X}$  must be of full column rank, at least when projected into the null space of any equality constraints.  $\mathbf{A}_{in}$  is a matrix of coefficients defining the inequality constraints, while  $\mathbf{b}_{in}$  is a vector involved in defining the inequality constraints.

Quadratic programming is used to perform the solution. The method used is designed for maximum stability with least squares problems: i.e.  $\mathbf{X}'\mathbf{X}$  is not formed explicitly. See Gill et al. 1981.

## Value

The function returns an array containing the estimated parameter vector.

---

pdIdnot

---

*Overflow proof pdMat class for multiples of the identity matrix*

---

## Description

This set of functions is a modification of the `pdMat` class `pdIdent` from library `nlme`. The modification is to replace the log parameterization used in `pdMat` with a `notLog2` parameterization, since the latter avoids indefiniteness in the likelihood and associated convergence problems: the parameters also relate to variances rather than standard deviations, for consistency with the `pdTens` class. The functions are particularly useful for working with Generalized Additive Mixed Models where variance parameters/smoothing parameters can be very large or very small, so that overflow or underflow can be a problem.

These functions would not normally be called directly, although unlike the `pdTens` class it is easy to do so.

## Usage

```

pdIdnot(value = numeric(0), form = NULL,
        nam = NULL, data = sys.frame(sys.parent()))

```

**Arguments**

value	Initialization values for parameters. Not normally used.
form	A one sided formula specifying the random effects structure.
nam	a names argument, not normally used with this class.
data	data frame in which to evaluate formula.

**Details**

The following functions are provided: `Dim.pdIndot`, `coef.pdIdnot`, `corMatrix.pdIdnot`, `logDet.pdIdnot`, `pdConstruct.pdIdnot`, `pdFactor.pdIdnot`, `pdMatrix.pdIdnot`, `solve.pdIdnot`, `summary.pdIdnot`. (e.g. `mgcv:::coef.pdIdnot` to access.)

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is initialised with estimates of the scaled covariance matrix itself.

**Value**

A class `pdIdnot` object, or related quantities. See the `nlme` documentation for further details.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**See Also**

[te](#), [pdTens](#), [notLog2](#), [gamm](#)

**Examples**

```
# see gamm
```

## Description

This set of functions implements an nlme library `pdMat` class to allow tensor product smooths to be estimated by `lme` as called by `gamm`. Tensor product smooths have a penalty matrix made up of a weighted sum of penalty matrices, where the weights are the smoothing parameters. In the mixed model formulation the penalty matrix is the inverse of the covariance matrix for the random effects of a term, and the smoothing parameters (times a half) are variance parameters to be estimated. It's not possible to transform the problem to make the required random effects covariance matrix look like one of the standard `pdMat` classes: hence the need for the `pdTens` class. A `notLog2` parameterization ensures that the parameters are positive.

These functions (`pdTens`, `pdConstruct.pdTens`, `pdFactor.pdTens`, `pdMatrix.pdTens`, `coef.pdTens` and `summary.pdTens`) would not normally be called directly.

## Usage

```
pdTens(value = numeric(0), form = NULL,
       nam = NULL, data = sys.frame(sys.parent()))
```

## Arguments

<code>value</code>	Initialization values for parameters. Not normally used.
<code>form</code>	A one sided formula specifying the random effects structure. The formula should have an attribute <code>S</code> which is a list of the penalty matrices the weighted sum of which gives the inverse of the covariance matrix for these random effects.
<code>nam</code>	a names argument, not normally used with this class.
<code>data</code>	data frame in which to evaluate formula.

## Details

If using this class directly note that it is worthwhile scaling the `S` matrices to be of 'moderate size', for example by dividing each matrix by its largest singular value: this avoids problems with `lme` defaults (`smooth.construct.tensor.smooth.spec` does this automatically).

This appears to be the minimum set of functions required to implement a new `pdMat` class.

Note that while the `pdFactor` and `pdMatrix` functions return the inverse of the scaled random effect covariance matrix or its factor, the `pdConstruct` function is sometimes initialised with estimates of the scaled covariance matrix, and sometimes initialized with its inverse.

## Value

A class `pdTens` object, or its coefficients or the matrix it represents or the factor of that matrix. `pdFactor` returns the factor as a vector (packed column-wise) (`pdMatrix` always returns a matrix).

---

pen.edf	<i>Extract the effective degrees of freedom associated with each penalty in a gam fit</i>
---------	---

---

**Description**

Finds the coefficients penalized by each penalty and adds up their effective degrees of freedom. Very useful for [t2](#) terms, but hard to interpret for terms where the penalties penalize overlapping sets of parameters (e.g. [te](#) terms).

**Usage**

```
pen.edf(x)
```

**Arguments**

x	an object inheriting from gam
---	-------------------------------

**Details**

Useful for models containing [t2](#) terms, since it splits the EDF for the term up into parts due to different components of the smooth. This is useful for figuring out which interaction terms are actually needed in a model.

**Value**

A vector of EDFs, named with labels identifying which penalty each EDF relates to.

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

**See Also**[t2](#)**Examples**

```
require(mgcv)
set.seed(20)
dat <- gamSim(1,n=400,scale=2) ## simulate data
## following `t2' smooth basically separates smooth
## of x0,x1 into main effects + interaction....

b <- gam(y~t2(x0,x1,bs="tp",m=1,k=7)+s(x2)+s(x3),
         data=dat,method="ML")
```

```

pen.edf(b)

## label "rr" indicates interaction edf (range space times range space)
## label "nr" (null space for x0 times range space for x1) is main
##           effect for x1.
## label "rn" is main effect for x0
## clearly interaction is negligible

## second example with higher order marginals.

b <- gam(y~t2(x0,x1,bs="tp",m=2,k=7,full=TRUE)
        +s(x2)+s(x3),data=dat,method="ML")
pen.edf(b)

## In this case the EDF is negligible for all terms in the t2 smooth
## apart from the `main effects' (r2 and 2r). To understand the labels
## consider the following 2 examples....
## "r1" relates to the interaction of the range space of the first
##     marginal smooth and the first basis function of the null
##     space of the second marginal smooth
## "2r" relates to the interaction of the second basis function of
##     the null space of the first marginal smooth with the range
##     space of the second marginal smooth.

```

---

place.knots

*Automatically place a set of knots evenly through covariate values*

---

## Description

Given a univariate array of covariate values, places a set of knots for a regression spline evenly through the covariate values.

## Usage

```
place.knots(x, nk)
```

## Arguments

x	array of covariate values (need not be sorted).
nk	integer indicating the required number of knots.

## Details

Places knots evenly throughout a set of covariates. For example, if you had 11 covariate values and wanted 6 knots then a knot would be placed at the first (sorted) covariate value and every second (sorted) value thereafter. With less convenient numbers of data and knots the knots are placed within intervals between data in order to achieve even coverage, where even means having approximately the same number of data between each pair of knots.

## Value

An array of knot locations.

require(mgcv)
x<-runif(30)
place.knots(x,7)
rm(x)
```

---

plot.gam	<i>Default GAM plotting</i>
----------	-----------------------------

---

**Description**

Takes a fitted gam object produced by `gam()` and plots the component smooth functions that make it up, on the scale of the linear predictor. Optionally produces term plots for parametric model components as well.

**Usage**

```
## S3 method for class 'gam'
plot(x, residuals=FALSE, rug=TRUE, se=TRUE, pages=0, select=NULL, scale=-1,
      n=100, n2=40, pers=FALSE, theta=30, phi=30, jit=FALSE, xlab=NULL,
      ylab=NULL, main=NULL, ylim=NULL, xlim=NULL, too.far=0.1,
      all.terms=FALSE, shade=FALSE, shade.col="gray80", shift=0,
      trans=I, seWithMean=FALSE, unconditional=FALSE, by.resids=FALSE,
      scheme=0, ...)
```

**Arguments**

<code>x</code>	a fitted gam object as produced by <code>gam()</code> .
<code>residuals</code>	If TRUE then partial residuals are added to plots of 1-D smooths. If FALSE then no residuals are added. If this is an array of the correct length then it is used as the array of residuals to be used for producing partial residuals. If TRUE then the residuals are the working residuals from the IRLS iteration weighted by the IRLS weights. Partial residuals for a smooth term are the residuals that would be obtained by dropping the term concerned from the model, while leaving all other estimates fixed (i.e. the estimates for the term plus the residuals).
<code>rug</code>	when TRUE (default) then the covariate to which the plot applies is displayed as a rug plot at the foot of each plot of a 1-d smooth, and the locations of the covariates are plotted as points on the contour plot representing a 2-d smooth. Setting to FALSE will speed up plotting for large datasets.

<code>se</code>	when TRUE (default) upper and lower lines are added to the 1-d plots at 2 standard errors above and below the estimate of the smooth being plotted while for 2-d plots, surfaces at +1 and -1 standard errors are contoured and overlaid on the contour plot for the estimate. If a positive number is supplied then this number is multiplied by the standard errors when calculating standard error curves or surfaces. See also <code>shade</code> , below.
<code>pages</code>	(default 0) the number of pages over which to spread the output. For example, if <code>pages=1</code> then all terms will be plotted on one page with the layout performed automatically. Set to 0 to have the routine leave all graphics settings as they are.
<code>select</code>	Allows the plot for a single model term to be selected for printing. e.g. if you just want the plot for the second smooth term set <code>select=2</code> .
<code>scale</code>	set to -1 (default) to have the same y-axis scale for each plot, and to 0 for a different y axis for each plot. Ignored if <code>ylim</code> supplied.
<code>n</code>	number of points used for each 1-d plot - for a nice smooth plot this needs to be several times the estimated degrees of freedom for the smooth. Default value 100.
<code>n2</code>	Square root of number of points used to grid estimates of 2-d functions for contouring.
<code>pers</code>	Set to TRUE if you want perspective plots for 2-d terms.
<code>theta</code>	One of the perspective plot angles.
<code>phi</code>	The other perspective plot angle.
<code>jit</code>	Set to TRUE if you want rug plots for 1-d terms to be jittered.
<code>xlab</code>	If supplied then this will be used as the x label for all plots.
<code>ylab</code>	If supplied then this will be used as the y label for all plots.
<code>main</code>	Used as title (or z axis label) for plots if supplied.
<code>ylim</code>	If supplied then this pair of numbers are used as the y limits for each plot.
<code>xlim</code>	If supplied then this pair of numbers are used as the x limits for each plot.
<code>too.far</code>	If greater than 0 then this is used to determine when a location is too far from data to be plotted when plotting 2-D smooths. This is useful since smooths tend to go wild away from data. The data are scaled into the unit square before deciding what to exclude, and <code>too.far</code> is a distance within the unit square. Setting to zero can make plotting faster for large datasets, but care then needed with interpretation of plots.
<code>all.terms</code>	if set to TRUE then the partial effects of parametric model components are also plotted, via a call to <code>termplot</code> . Only terms of order 1 can be plotted in this way.
<code>shade</code>	Set to TRUE to produce shaded regions as confidence bands for smooths (not available for parametric terms, which are plotted using <code>termplot</code> ).
<code>shade.col</code>	define the color used for shading confidence bands.
<code>shift</code>	constant to add to each smooth (on the scale of the linear predictor) before plotting. Can be useful for some diagnostics, or with <code>trans</code> .
<code>trans</code>	function to apply to each smooth (after any shift), before plotting. <code>shift</code> and <code>trans</code> are occasionally useful as a means for getting plots on the response scale, when the model consists only of a single smooth.

<code>seWithMean</code>	if TRUE the component smooths are shown with confidence intervals that include the uncertainty about the overall mean. If FALSE then the uncertainty relates purely to the centred smooth itself. Marra and Wood (2012) suggests that TRUE results in better coverage performance, and this is also suggested by simulation.
<code>unconditional</code>	if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used to compute uncertainty bands, if available. Otherwise the bands treat the smoothing parameters as fixed.
<code>by.resids</code>	Should partial residuals be plotted for terms with <code>by</code> variables? Usually the answer is no, they would be meaningless.
<code>scheme</code>	Integer or integer vector selecting a plotting scheme for each plot. See details.
<code>...</code>	other graphics parameters to pass on to plotting commands. See details for smooth plot specific options.

## Details

Produces default plot showing the smooth components of a fitted GAM, and optionally parametric terms as well, when these can be handled by `termplot`.

For smooth terms `plot.gam` actually calls plot method functions depending on the class of the smooth. Currently `random.effects`, Markov random fields (`mrf`), `Spherical.Spline` and `factor.smooth.interaction` terms have special methods (documented in their help files), the rest use the defaults described below.

For plots of 1-d smooths, the x axis of each plot is labelled with the covariate name, while the y axis is labelled `s(cov, edf)` where `cov` is the covariate name, and `edf` the estimated (or user defined for regression splines) degrees of freedom of the smooth. `scheme == 0` produces a smooth curve with dashed curves indicating 2 standard error bounds. `scheme == 1` illustrates the error bounds using a shaded region.

For `scheme==0`, contour plots are produced for 2-d smooths with the x-axes labelled with the first covariate name and the y axis with the second covariate name. The main title of the plot is something like `s(var1, var2, edf)`, indicating the variables of which the term is a function, and the estimated degrees of freedom for the term. When `se=TRUE`, estimator variability is shown by overlaying contour plots at plus and minus 1 s.e. relative to the main estimate. If `se` is a positive number then contour plots are at plus or minus `se` multiplied by the s.e. Contour levels are chosen to try and ensure reasonable separation of the contours of the different plots, but this is not always easy to achieve. Note that these plots can not be modified to the same extent as the other plot.

For 2-d smooths `scheme==1` produces a perspective plot, while `scheme==2` produces a heatmap, with overlaid contours.

Smooths of more than 2 variables are not plotted, but see `vis.gam`.

Fine control of plots for parametric terms can be obtained by calling `termplot` directly, taking care to use its `terms` argument.

Note that, if `seWithMean=TRUE`, the confidence bands include the uncertainty about the overall mean. In other words although each smooth is shown centred, the confidence bands are obtained as if every other term in the model was constrained to have average 0, (average taken over the covariate values), except for the smooth concerned. This seems to correspond more closely to how most users interpret componentwise intervals in practice, and also results in intervals with close to nominal (frequentist) coverage probabilities by an extension of Nychka's (1988) results presented in Marra and Wood (2012).

Several smooth plots methods using `image` will accept a `colors` argument, which can be anything documented in `heat.colors` (in which case something like `colors=rainbow(50)` is

appropriate), or the `grey` function (in which case something like `colors=grey(0:50/50)` is needed). Another option is `contour.col` which will set the contour colour for some plots. These options are useful for producing grey scale pictures instead of colour.

Sometimes you may want a small change to a default plot, and the arguments to `plot.gam` just won't let you do it. In this case, the quickest option is sometimes to clone the `smooth.construct` and `Predict.matrix` methods for the smooth concerned, modifying only the returned smoother class (e.g. to `foo.smooth`). Then copy the plot method function for the original class (e.g. `mgcv::plot.mgcv.smooth`), modify the source code to plot exactly as you want and rename the plot method function (e.g. `plot.foo.smooth`). You can then use the cloned smooth in models (e.g. `s(x, bs="foo")`), and it will automatically plot using the modified plotting function.

### Value

The functions main purpose is its side effect of generating plots. It also silently returns a list of the data used to produce the plots, which can be used to generate customized plots.

### WARNING

Note that the behaviour of this function is not identical to `plot.gam()` in S-PLUS.

Plotting can be slow for models fitted to large datasets. Set `rug=FALSE` to improve matters. If it's still too slow set `too.far=0`, but then take care not to overinterpret smooths away from supporting data.

Plots of 2-D smooths with standard error contours shown can not easily be customized.

The function can not deal with smooths of more than 2 variables!

### Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

Henric Nilsson <[henric.nilsson@statisticon.se](mailto:henric.nilsson@statisticon.se)> donated the code for the `shade` option.

The design is inspired by the S function of the same name described in Chambers and Hastie (1993) (but is not a clone).

---

polys.plot

*Plot geographic regions defined as polygons*

---

### Description

Produces plots of geographic regions defined by polygons, optionally filling the polygons with a color or grey shade dependent on a covariate.

### Usage

```
polys.plot(pc, z=NULL, scheme="heat", lab="", ...)
```

### Arguments

<code>pc</code>	A named list of matrices. Each matrix has two columns. The matrix rows each define the vertex of a boundary polygon. If a boundary is defined by several polygons, then each of these must be separated by an NA row in the matrix. See <a href="#">mrf</a> for an example.
<code>z</code>	A vector of values associated with each area (item) of <code>pc</code> . If the vector elements have names then these are used to match elements of <code>z</code> to areas defined in <code>pc</code> . Otherwise <code>pc</code> and <code>z</code> are assumed to be in the same order. If <code>z</code> is <code>NULL</code> then polygons are not filled.
<code>scheme</code>	One of "heat" or "grey", indicating how to fill the polygons in accordance with the value of <code>z</code> .
<code>lab</code>	label for plot.
<code>...</code>	other arguments to pass to plot (currently only if <code>z</code> is <code>NULL</code> ).

### Details

Any polygon within another polygon counts as a hole in the area. Further nesting is dealt with by treating any point that is interior to an odd number of polygons as being within the area, and all other points as being exterior. The routine is provided to facilitate plotting with models containing [mrf](#) smooths.

### Value

Simply produces a plot.

### Author(s)

Simon Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

predict.bam

*Prediction from fitted Big Additive Model model***Description**

Essentially a wrapper for `predict.gam` for prediction from a model fitted by `bam`. Can compute on a parallel cluster.

Takes a fitted `bam` object produced by `bam` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

**Usage**

```
## S3 method for class 'bam'
predict(object, newdata, type="link", se.fit=FALSE, terms=NULL,
        exclude=NULL, block.size=50000, newdata.guaranteed=FALSE,
        na.action=na.pass, cluster=NULL, ...)
```

**Arguments**

<code>object</code>	a fitted <code>bam</code> object as produced by <code>bam</code> .
<code>newdata</code>	A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If <code>newdata</code> is provided then it should contain all the variables needed for prediction: a warning is generated if not.
<code>type</code>	When this has the value "link" (default) the linear predictor (possibly with associated standard errors) is returned. When <code>type="terms"</code> each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component, but excludes any offset and any intercept. <code>type="iterms"</code> is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When <code>type="response"</code> predictions on the scale of the response are returned (possibly with approximate standard errors). When <code>type="lpmatrix"</code> then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case <code>se.fit</code> is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).
<code>se.fit</code>	when this is TRUE (not default) standard error estimates are returned for each prediction.
<code>terms</code>	if <code>type=="terms"</code> or <code>type="iterms"</code> then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If NULL then all terms are included.

<code>exclude</code>	if <code>type=="terms"</code> or <code>type="iterms"</code> then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If <code>NULL</code> then no terms are excluded.
<code>block.size</code>	maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive.
<code>newdata.guaranteed</code>	Set to <code>TRUE</code> to turn off all checking of <code>newdata</code> except for sanity of factor levels: this can speed things up for large prediction tasks, but <code>newdata</code> must be complete, with no NA values for predictors required in the model.
<code>na.action</code>	what to do about NA values in <code>newdata</code> . With the default <code>na.pass</code> , any row of <code>newdata</code> containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). <code>na.exclude</code> or <code>na.omit</code> result in the dropping of <code>newdata</code> rows, if they contain any NA values for required predictors. If <code>newdata</code> is missing then NA handling is determined from <code>object\$na.action</code> .
<code>cluster</code>	<code>predict.bam</code> can compute in parallel using <a href="#">parLapply</a> from the <code>parallel</code> package, if it is supplied with a cluster on which to do this (a cluster here can be some cores of a single machine). See details and example code for <a href="#">bam</a> .
<code>...</code>	other arguments.

### Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted `bam` object.

To facilitate plotting with [termplot](#), if `object` possesses an attribute `"para.only"` and `type=="terms"` then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to [gam](#) as an argument is always ignored when predicting, unlike offsets specified in the `gam` model formula.

See the examples in [predict.gam](#) for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

### Value

If `type=="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is `TRUE` then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is `"terms"` or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or `model.frame`: if it's a `model.frame` then all variables must be supplied.

<code>predict.gam</code>	<i>Prediction from fitted GAM model</i>
--------------------------	---

---

## Description

Takes a fitted `gam` object produced by `gam()` and produces predictions given a new set of values for the model covariates or the original values used for the model fit. Predictions can be accompanied by standard errors, based on the posterior distribution of the model coefficients. The routine can optionally return the matrix by which the model coefficients must be pre-multiplied in order to yield the values of the linear predictor at the supplied covariate values: this is useful for obtaining credible regions for quantities derived from the model (e.g. derivatives of smooths), and for lookup table prediction outside R (see example code below).

## Usage

```
## S3 method for class 'gam'
predict(object, newdata, type="link", se.fit=FALSE, terms=NULL,
        exclude=NULL, block.size=NULL, newdata.guaranteed=FALSE,
        na.action=na.pass, unconditional=FALSE, ...)
```

## Arguments

<code>object</code>	a fitted <code>gam</code> object as produced by <code>gam()</code> .
<code>newdata</code>	A data frame or list containing the values of the model covariates at which predictions are required. If this is not provided then predictions corresponding to the original data are returned. If <code>newdata</code> is provided then it should contain all the variables needed for prediction: a warning is generated if not.
<code>type</code>	When this has the value <code>"link"</code> (default) the linear predictor (possibly with associated standard errors) is returned. When <code>type="terms"</code> each component of the linear predictor is returned separately (possibly with standard errors): this includes parametric model components, followed by each smooth component,

	but excludes any offset and any intercept. <code>type="iterms"</code> is the same, except that any standard errors returned for smooth components will include the uncertainty about the intercept/overall mean. When <code>type="response"</code> predictions on the scale of the response are returned (possibly with approximate standard errors). When <code>type="lpmatrix"</code> then a matrix is returned which yields the values of the linear predictor (minus any offset) when postmultiplied by the parameter vector (in this case <code>se.fit</code> is ignored). The latter option is most useful for getting variance estimates for quantities derived from the model: for example integrated quantities, or derivatives of smooths. A linear predictor matrix can also be used to implement approximate prediction outside R (see example code, below).
<code>se.fit</code>	when this is TRUE (not default) standard error estimates are returned for each prediction.
<code>terms</code>	if <code>type=="terms"</code> or <code>type="iterms"</code> then only results for the terms (smooth or parametric) named in this array will be returned. Otherwise any smooth terms not named in this array will be set to zero. If NULL then all terms are included.
<code>exclude</code>	if <code>type=="terms"</code> or <code>type="iterms"</code> then terms (smooth or parametric) named in this array will not be returned. Otherwise any smooth terms named in this array will be set to zero. If NULL then no terms are excluded.
<code>block.size</code>	maximum number of predictions to process per call to underlying code: larger is quicker, but more memory intensive. Set to $< 1$ to use total number of predictions as this. If NULL then block size is 1000 if new data supplied, and the number of rows in the model frame otherwise.
<code>newdata.guaranteed</code>	Set to TRUE to turn off all checking of <code>newdata</code> except for sanity of factor levels: this can speed things up for large prediction tasks, but <code>newdata</code> must be complete, with no NA values for predictors required in the model.
<code>na.action</code>	what to do about NA values in <code>newdata</code> . With the default <code>na.pass</code> , any row of <code>newdata</code> containing NA values for required predictors, gives rise to NA predictions (even if the term concerned has no NA predictors). <code>na.exclude</code> or <code>na.omit</code> result in the dropping of <code>newdata</code> rows, if they contain any NA values for required predictors. If <code>newdata</code> is missing then NA handling is determined from <code>object\$na.action</code> .
<code>unconditional</code>	if TRUE then the smoothing parameter uncertainty corrected covariance matrix is used, when available, otherwise the covariance matrix conditional on the estimated smoothing parameters is used.
<code>...</code>	other arguments.

## Details

The standard errors produced by `predict.gam` are based on the Bayesian posterior covariance matrix of the parameters  $V_p$  in the fitted gam object.

To facilitate plotting with `termplot`, if `object` possesses an attribute `"para.only"` and `type=="terms"` then only parametric terms of order 1 are returned (i.e. those that `termplot` can handle).

Note that, in common with other prediction functions, any offset supplied to `gam` as an argument is always ignored when predicting, unlike offsets specified in the gam model formula.

See the examples for how to use the `lpmatrix` for obtaining credible regions for quantities derived from the model.

**Value**

If `type=="lpmatrix"` then a matrix is returned which will give a vector of linear predictor values (minus any offset) at the supplied covariate values, when applied to the model coefficient vector. Otherwise, if `se.fit` is `TRUE` then a 2 item list is returned with items (both arrays) `fit` and `se.fit` containing predictions and associated standard error estimates, otherwise an array of predictions is returned. The dimensions of the returned arrays depends on whether `type` is `"terms"` or not: if it is then the array is 2 dimensional with each term in the linear predictor separate, otherwise the array is 1 dimensional and contains the linear predictor/predicted values (or corresponding s.e.s). The linear predictor returned termwise will not include the offset or the intercept.

`newdata` can be a data frame, list or model.frame: if it's a model frame then all variables must be supplied.

**WARNING**

Note that the behaviour of this function is not identical to `predict.gam()` in `Splu`.

`type=="terms"` does not exactly match what `predict.lm` does for parametric model components.

}

```

## Description

Takes smooth objects produced by `smooth.construct` methods and obtains the matrix mapping the parameters associated with such a smooth to the predicted values of the smooth at a set of new covariate values.

In practice this method is often called via the wrapper function `PredictMat`.

### Usage

```
Predict.matrix(object, data)
Predict.matrix2(object, data)
```

### Arguments

<code>object</code>	is a smooth object produced by a <code>smooth.construct</code> method function. The object contains all the information required to specify the basis for a term of its class, and this information is used by the appropriate <code>Predict.matrix</code> function to produce a prediction matrix for new covariate values. Further details are given in <code>smooth.construct</code> .
<code>data</code>	A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <code>smooth.construct</code> and <code>smooth.construct2</code> .

### Details

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. The `Predict.matrix` functions are used to obtain the matrix that will map the parameters associated with a smooth term to the predicted values for the term at new covariate values.

Note that new smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function: see the example code provided for `smooth.construct` for details.

### Value

A matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`. If the smooth class is one which generates offsets the corresponding offset is returned as attribute `"offset"` of the matrix.

---

`Predict.matrix.cr.smooth`*Predict matrix method functions*

---

## Description

The various built in smooth classes for use with [gam](#) have associate `Predict.matrix` method functions to enable prediction from the fitted model.

## Usage

```
## S3 method for class 'cr.smooth'
Predict.matrix(object, data)
## S3 method for class 'cs.smooth'
Predict.matrix(object, data)
## S3 method for class 'cyclic.smooth'
Predict.matrix(object, data)
## S3 method for class 'pspline.smooth'
Predict.matrix(object, data)
## S3 method for class 'tensor.smooth'
Predict.matrix(object, data)
## S3 method for class 'tprs.smooth'
Predict.matrix(object, data)
## S3 method for class 'ts.smooth'
Predict.matrix(object, data)
## S3 method for class 't2.smooth'
Predict.matrix(object, data)
```

## Arguments

<code>object</code>	a smooth object, usually generated by a <a href="#">smooth.construct</a> method having processed a smooth specification object generated by an <code>s</code> or <code>te</code> term in a <a href="#">gam</a> formula.
<code>data</code>	A data frame containing the values of the (named) covariates at which the smooth term is to be evaluated. Exact requirements are as for <a href="#">smooth.construct</a> and <code>smooth.construct2</code> .

## Details

The Predict matrix function is not normally called directly, but is rather used internally by [predict.gam](#) etc. to predict from a fitted [gam](#) model. See [Predict.matrix](#) for more details, or the specific `smooth.construct` pages for details on a particular smooth class.

## Value

A matrix mapping the coefficients for the smooth term to its values at the supplied data values.

## Author(s)

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

## References

Wood S.N. (2006) Generalized Additive Models: An Introduction with R. Chapman and Hall/CRC Press.

## Examples

```
## see smooth.construct
```

---

```
Predict.matrix.soap.film
```

*Prediction matrix for soap film smooth*

---

## Description

Creates a prediction matrix for a soap film smooth object, mapping the coefficients of the smooth to the linear predictor component for the smooth. This is the `Predict.matrix` method function required by `gam`.

## Usage

```
## S3 method for class 'soap.film'
Predict.matrix(object, data)
## S3 method for class 'sw'
Predict.matrix(object, data)
## S3 method for class 'sf'
Predict.matrix(object, data)
```

## Arguments

<code>object</code>	A class "soap.film", "sf" or "sw" object.
<code>data</code>	A list list or data frame containing the arguments of the smooth at which predictions are required.

## Details

The smooth object will be largely what is returned from `smooth.construct.so.smooth.spec`, although elements `X` and `S` are not needed, and need not be present, of course.

## Value

A matrix. This may have an "offset" attribute corresponding to the contribution from any known boundary conditions on the smooth.

```

---

print.gam

---

*Print a Generalized Additive Model object.*

---

## Description

The default print method for a gam object.

## Usage

```
## S3 method for class 'gam'
print(x, ...)
```

## Arguments

`x, ...` fitted model objects of class gam as produced by `gam()`.

## Details

Prints out the family, model formula, effective degrees of freedom for each smooth term, and optimized value of the smoothness selection criterion used. See [gamObject](#) (or `names(x)`) for a listing of what the object contains. [summary.gam](#) provides more detail.

Note that the optimized smoothing parameter selection criterion reported is one of GCV, UBRE(AIC), GACV, negative log marginal likelihood (ML), or negative log restricted likelihood (REML).

If rank deficiency of the model was detected then the apparent rank is reported, along with the length of the coefficient vector (rank in absense of rank deficieny). Rank deficiency occurs when not all coefficients are identifiable given the data. Although the fitting routines (except `gamm`) deal gracefully with rank deficiency, interpretation of rank deficient models may be difficult.

---

qq.gam	<i>QQ plots for gam model residuals</i>
--------	---

---

### Description

Takes a fitted `gam` object produced by `gam()` and produces QQ plots of its residuals (conditional on the fitted model coefficients and scale parameter). If the model distributional assumptions are met then usually these plots should be close to a straight line (although discrete data can yield marked random departures from this line).

### Usage

```
qq.gam(object, rep=0, level=.9, s.rep=10,
        type=c("deviance", "pearson", "response"),
        pch=".", rl.col=2, rep.col="gray80", ...)
```

### Arguments

<code>object</code>	a fitted <code>gam</code> object as produced by <code>gam()</code> (or a <code>glm</code> object).
<code>rep</code>	How many replicate datasets to generate to simulate quantiles of the residual distribution. 0 results in an efficient simulation free method for direct calculation, if this is possible for the object family.
<code>level</code>	If simulation is used for the quantiles, then reference intervals can be provided for the QQ-plot, this specifies the level. 0 or less for no intervals, 1 or more to simply plot the QQ plot for each replicate generated.
<code>s.rep</code>	how many times to randomize uniform quantiles to data under direct computation.
<code>type</code>	what sort of residuals should be plotted? See <a href="#">residuals.gam</a> .
<code>pch</code>	plot character to use. 19 is good.
<code>rl.col</code>	color for the reference line on the plot.
<code>rep.col</code>	color for reference bands or replicate reference plots.
<code>...</code>	extra graphics parameters to pass to plotting functions.

## Details

QQ-plots of the the model residuals can be produced in one of two ways. The cheapest method generates reference quantiles by associating a quantile of the uniform distribution with each datum, and feeding these uniform quantiles into the quantile function associated with each datum. The resulting quantiles are then used in place of each datum to generate approximate quantiles of residuals. The residual quantiles are averaged over `s.rep` randomizations of the uniform quantiles to data.

The second method is to use direct simulation. For each replicate, data are simulated from the fitted model, and the corresponding residuals computed. This is repeated `rep` times. Quantiles are readily obtained from the empirical distribution of residuals so obtained. From this method reference bands are also computable.

Even if `rep` is set to zero, the routine will attempt to simulate quantiles if no quantile function is available for the family. If no random deviate generating function family is available (e.g. for the quasi families), then a normal QQ-plot is produced. The routine conditions on the fitted model coefficients and the scale parameter estimate.

The plots are very similar to those proposed in Ben and Yohai (2004), but are substantially cheaper to produce (the interpretation of residuals for binary data in Ben and Yohai is not recommended).

Note that plots for raw residuals from fits to binary data contain almost no useful information about model fit. Whether the residual is negative or positive is decided by whether the response is zero or one. The magnitude of the residual, given its sign, is determined entirely by the fitted values. In consequence only the most gross violations of the model are detectable from QQ-plots of residuals for binary data. To really check distributional assumptions from residuals for binary data you have to be able to group the data somehow. Binomial models other than binary are ok.

plot(b, residuals=TRUE, pch=19, cex=.3)

```

## Description

The smooth components of GAMs can be viewed as random effects for estimation purposes. This means that more conventional random effects terms can be incorporated into GAMs in two ways. The first method converts all the smooths into fixed and random components suitable for estimation

by standard mixed modelling software. Once the GAM is in this form then conventional random effects are easily added, and the whole model is estimated as a general mixed model. `gamm` and `gamm4` from the `gamm4` package operate in this way.

The second method represents the conventional random effects in a GAM in the same way that the smooths are represented — as penalized regression terms. This method can be used with `gam` by making use of `s(...,bs="re")` terms in a model: see `smooth.construct.re.smooth.spec`, for full details. The basic idea is that, e.g., `s(x,z,g,bs="re")` generates an i.i.d. Gaussian random effect with model matrix given by `model.matrix(~x:z:g-1)` — in principle such terms can take any number of arguments. This simple approach is sufficient for implementing a wide range of commonly used random effect structures. For example if `g` is a factor then `s(g,bs="re")` produces a random coefficient for each level of `g`, with the random coefficients all modelled as i.i.d. normal. If `g` is a factor and `x` is numeric, then `s(x,g,bs="re")` produces an i.i.d. normal random slope relating the response to `x` for each level of `g`. If `h` is another factor then `s(h,g,bs="re")` produces the usual i.i.d. normal `g - h` interaction. Note that a rather useful approximate test for zero random effect is also implemented for such terms based on Wood (2013).

Alternatively, but less straightforwardly, the `paraPen` argument to `gam` can be used: see `gam.models`. If smoothing parameter estimation is by ML or REML (e.g. `gam(...,method="REML")`) then this approach is a completely conventional likelihood based treatment of random effects.

`gam` can be slow for fitting models with large numbers of random effects, because it does not exploit the sparsity that is often a feature of parametric random effects. It can not be used for models with more coefficients than data. However `gam` is often faster and more reliable than `gamm` or `gamm4`, when the number of random effects is modest.

To facilitate the use of random effects with `gam`, `gam.vcomp` is a utility routine for converting smoothing parameters to variance components. It also provides confidence intervals, if smoothness estimation is by ML or REML.

Note that treating random effects as smooths does not remove the usual problems associated with testing variance components for equality to zero: see `summary.gam` and `anova.gam`.

residuals.gam

*Generalized Additive Model residuals*

---

## Description

Returns residuals for a fitted `gam` model object. Pearson, deviance, working and response residuals are available.

## Usage

```
## S3 method for class 'gam'
residuals(object, type = "deviance", ...)
```

## Arguments

<code>object</code>	a <code>gam</code> fitted model object.
<code>type</code>	the type of residuals wanted. Usually one of "deviance", "pearson", "scaled.pearson", "working", or "response".
<code>...</code>	other arguments.

## Details

Response residuals are the raw residuals (data minus fitted values). Scaled Pearson residuals are raw residuals divided by the standard deviation of the data according to the model mean variance relationship and estimated scale parameter. Pearson residuals are the same, but multiplied by the square root of the scale parameter (so they are independent of the scale parameter):  $((y - \mu) / \sqrt{V(\mu)})$ , where  $y$  is data  $\mu$  is model fitted value and  $V$  is model mean-variance relationship.). Both are provided since not all texts agree on the definition of Pearson residuals. Deviance residuals simply return the deviance residuals defined by the model family. Working residuals are the residuals returned from model fitting at convergence.

Families can supply their own residual function, which is used in place of the standard function if present, (e.g. [cox.ph](#)).

## Value

A vector of residuals.

rig

*Generate inverse Gaussian random deviates*

---

**Description**

Generates inverse Gaussian random deviates.

**Usage**

```
rig(n, mean, scale)
```

**Arguments**

n	the number of deviates required. If this has length > 1 then the length is taken as the number of deviates required.
mean	vector of mean values.
scale	vector of scale parameter values (lambda, see below)

**Details**

If  $x$  is the returned vector, then  $E(x) = \text{mean}$  while  $\text{var}(x) = \text{scale} * \text{mean}^3$ . For density and distribution functions see the `statmod` package. The algorithm used is Algorithm 5.7 of Gentle (2003), based on Michael et al. (1976). Note that `scale` here is the scale parameter in the GLM sense, which is the reciprocal of the usual 'lambda' parameter.

**Value**

A vector of inverse Gaussian random deviates.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

dat$y <- rig(Ey,mean=Ey,scale=.2)
big <- gam(y~ s(x0)+ s(x1)+s(x2)+s(x3),family=inverse.gaussian(link=log),
          data=dat,method="REML")
plot(big,pages=1)
gam.check(big)
summary(big)
```

rmvn

*Generate multivariate normal deviates*

## Description

Generates multivariate normal random deviates.

## Usage

```
rmvn(n, mu, V)
```

## Arguments

n	number of simulated vectors required.
mu	the mean of the vectors: either a single vector of length $p = \text{ncol}(V)$ or an $n$ by $p$ matrix.
V	A positive semi definite covariance matrix.

## Details

Uses a ‘square root’ of  $V$  to transform stadard normal deviates to multivariate normal with the correct covariance matrix.

## Value

An  $n$  row matrix, with each row being a draw from a multivariate normal density with covariance matrix  $V$  and mean vector  $\mu$ . Alternatively each row may have a different mean vector if  $\mu$  is a vector.

## Author(s)

V <- matrix(c(2,1,1,2),2,2)
mu <- c(1,3)
n <- 1000
z <- rmvn(n,mu,V)
crossprod(sweep(z,2,colMeans(z)))/n ## observed covariance matrix
colMeans(z) ## observed mu
```

---

Rrank

---

*Find rank of upper triangular matrix*

---

**Description**

Finds rank of upper triangular matrix R, by estimating condition number of upper rank by rank block, and reducing rank until this is acceptably low. Assumes R has been computed by a method that uses pivoting, usually pivoted QR or Choleski.

**Usage**

```
Rrank(R,tol=.Machine$double.eps^.9)
```

**Arguments**

R	An upper triangular matrix, obtained by pivoted QR or pivoted Choleski.
tol	the tolerance to use for judging rank.

**Details**

The method is based on Cline et al. (1979) as described in Golub and van Loan (1996).

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**References**

**Examples**

```
set.seed(0)
n <- 10;p <- 5
X <- matrix(runif(n*(p-1)),n,p)
qrx <- qr(X,LAPACK=TRUE)
Rrank(qr.R(qrx))
```

rTweedie

*Generate Tweedie random deviates***Description**

Generates Tweedie random deviates, for powers between 1 and 2.

**Usage**

```
rTweedie(mu, p=1.5, phi=1)
```

**Arguments**

mu	vector of expected values for the deviates to be generated. One deviate generated for each element of mu.
p	the variance of a deviate is proportional to its mean, mu to the power p. p must be between 1 and 2. 1 is Poisson like (exactly Poisson if phi=1), 2 is gamma.
phi	The scale parameter. Variance of the deviates is given by $\phi * \mu^p$ .

**Details**

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution, with mean  $\mu^{(2-p)} / ((2-p) * \phi)$ . The Gamma random variables that are summed have shape parameter  $(2-p) / (p-1)$  and scale parameter  $\phi * (p-1) * \mu^{(p-1)}$  (note that this scale parameter is different from the scale parameter for a GLM with Gamma errors).

This is a restricted, but faster, version of `rtweedie` from the `tweedie` package.

**Value**

A vector of random deviates from a Tweedie distribution, expected value vector mu, variance vector  $\phi * \mu^p$ .

**Author(s)**

Simon N. Wood <[simon.wood@r-project.org](mailto:simon.wood@r-project.org)>

  (10 * x)^3 * (1 - x)^10
n <- 300
x <- runif(n)
mu <- exp(f2(x)/3+.1); x <- x*10 - 4
y <- rTweedie(mu,p=1.5,phi=1.3)
b <- gam(y~s(x,k=20),family=Tweedie(p=1.5))
b
plot(b)
```

s

*Defining smooths in GAM formulae*

## Description

Function used in definition of smooth terms within `gam` model formulae. The function does not evaluate a (spline) smooth - it exists purely to help set up a model using spline based smooths.

## Usage

```
s(..., k=-1, fx=FALSE, bs="tp", m=NA, by=NA, xt=NULL, id=NULL, sp=NULL)
```

## Arguments

- |     |  |
|-----|--|
| ... | a list of variables that are the covariates that this smooth is a function of.   |
| k   | the dimension of the basis used to represent the smooth term. The default depends on the number of variables that the smooth is a function of. <code>k</code> should not be less than the dimension of the null space of the penalty for the term (see <a href="#">null.space.dimension</a> ), but will be reset if it is. See <a href="#">choose.k</a> for further information.   |
| fx  | indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).  |
| bs  | a two letter character string indicating the (penalized) smoothing basis to use. (eg "tp" for thin plate regression spline, "cr" for cubic regression spline). see <a href="#">smooth.terms</a> for an over view of what is available.   |
| m   | The order of the penalty for this term (e.g. 2 for normal cubic spline penalty with 2nd derivatives when using default t.p.r.s basis). NA signals autoinitialization. Only some smooth classes use this. The "ps" class can use a 2 item array giving the basis and penalty order separately.  |
| by  | a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth, evaluated at the corresponding covariate values (a 'varying coefficient model' results). For the numeric <code>by</code> variable case the resulting smooth is not usually subject to a centering constraint (so the <code>by</code> variable should not be added as an additional main effect). In the factor <code>by</code> variable case a replicate of the smooth is produced for each factor level (these smooths will be centered, so the factor usually needs to be added as a main effect as well). See <a href="#">gam.models</a> for further details. A <code>by</code> variable may |

also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see [gam.models](#) and [linear.functional.terms](#) for details).

<code>xt</code>	Any extra information required to set up a particular basis. Used e.g. to set large data set handling behaviour for "tp" basis.
<code>id</code>	A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more terms have the same <code>id</code> then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction). An <code>id</code> with a factor <code>by</code> variable causes the smooths at each factor level to have the same smoothing parameter.
<code>sp</code>	any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <code>sp</code> argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .

## Details

The function does not evaluate the variable arguments. To use this function to specify use of your own smooths, note the relationships between the inputs and the output object and see the example in [smooth.construct](#).

## Value

A class `xx.smooth.spec` object, where `xx` is a basis identifying code given by the `bs` argument of `s`. These `smooth.spec` objects define smooths and are turned into bases and penalties by `smooth.construct` method functions.

The returned object contains the following items:

<code>term</code>	An array of text strings giving the names of the covariates that the term is a function of.
<code>bs.dim</code>	The dimension of the basis used to represent the smooth.
<code>fixed</code>	TRUE if the term is to be treated as a pure regression spline (with fixed degrees of freedom); FALSE if it is to be treated as a penalized regression spline
<code>dim</code>	The dimension of the smoother - i.e. the number of covariates that it is a function of.
<code>p.order</code>	The order of the t.p.r.s. penalty, or 0 for auto-selection of the penalty order.
<code>by</code>	is the name of any <code>by</code> variable as text ("NA" for none).
<code>label</code>	A suitable text label for this smooth term.
<code>xt</code>	The object passed in as argument <code>xt</code> .
<code>id</code>	An identifying label or number for the smooth, linking it to other smooths. Defaults to NULL for no linkage.
<code>sp</code>	array of smoothing parameters for the term (negative for auto-estimation). Defaults to NULL.

scat

*GAM scaled t family for heavy tailed data*

---

## Description

Family for use with [gam](#), implementing regression for the heavy tailed response variables,  $y$ , using a scaled  $t$  model. The idea is that  $(y - \mu)/\sigma \sim t_\nu$  where  $\mu$  is determined by a linear predictor, while  $\sigma$  and  $\nu$  are parameters to be estimated alongside the smoothing parameters.

## Usage

```
scat(theta = NULL, link = "identity")
```

## Arguments

<code>theta</code>	the parameters to be estimated $\nu = 2 + \exp(\theta_1)$ and $\sigma = \exp(\theta_2)$ . If supplied and positive, then taken to be fixed values of $\nu$ and $\sigma$ . If any negative, then absolute values taken as starting values.
<code>link</code>	The link function: one of "identity", "log" or "inverse".

## Details

Useful in place of Gaussian, when data are heavy tailed.

**Value**

An object of class `extended.family`.

**Author(s)**

Natalya Pya (nyp20@bath.ac.uk)

**Examples**

```
library(mgcv)
## Simulate some t data...
set.seed(3); n<-400
dat <- gamSim(1, n=n)
dat$y <- dat$f + rt(n, df=3)*2

b <- gam(y~s(x0)+s(x1)+s(x2)+s(x3), family=scat(link="identity"), data=dat)

b
plot(b, pages=1)
```

---

single.index

---

Single index models with mgcv

---

**Description**

Single index models contain smooth terms with arguments that are linear combinations of other covariates. e.g.  $s(X\alpha)$  where  $\alpha$  has to be estimated. For identifiability, assume  $\|\alpha\| = 1$  with positive first element. One simple way to fit such models is to use [gam](#) to profile out the smooth model coefficients and smoothing parameters, leaving only the  $\alpha$  to be estimated by a general purpose optimizer.

Example code is provided below, which can be easily adapted to include multiple single index terms, parametric terms and further smooths. Note the initialization strategy. First estimate  $\alpha$  without penalization to get starting values and then do the full fit. Otherwise it is easy to get trapped in a local optimum in which the smooth is linear. An alternative is to initialize using fixed penalization (via the `sp` argument to [gam](#)).

diag(Vt)^.5

```

slanczos

*Compute truncated eigen decomposition of a symmetric matrix***Description**

Uses Lanczos iteration to find the truncated eigen-decomposition of a symmetric matrix.

**Usage**

```
slanczos(A, k=10, kl=-1, tol=.Machine$double.eps^.5, nt=1)
```

**Arguments**

<code>A</code>	A symmetric matrix.
<code>k</code>	Must be non-negative. If <code>kl</code> is negative, then the <code>k</code> largest magnitude eigenvalues are found, together with the corresponding eigenvectors. If <code>kl</code> is non-negative then the <code>k</code> highest eigenvalues are found together with their eigenvectors and the <code>kl</code> lowest eigenvalues with eigenvectors are also returned.
<code>kl</code>	If <code>kl</code> is non-negative then the <code>kl</code> lowest eigenvalues are returned together with their corresponding eigenvectors (in addition to the <code>k</code> highest eigenvalues + vectors). negative <code>kl</code> signals that the <code>k</code> largest magnitude eigenvalues should be returned, with eigenvectors.
<code>tol</code>	tolerance to use for convergence testing of eigenvalues. Error in eigenvalues will be less than the magnitude of the dominant eigenvalue multiplied by <code>tol</code> (or the machine precision!).
<code>nt</code>	number of threads to use for leading order iterative multiplication of <code>A</code> by vector. May show no speed improvement on two processor machine.

**Details**

If `kl` is non-negative, returns the highest `k` and lowest `kl` eigenvalues, with their corresponding eigenvectors. If `kl` is negative, returns the largest magnitude `k` eigenvalues, with corresponding eigenvectors.

The routine implements Lanczos iteration with full re-orthogonalization as described in Demmel (1997). Lanczos iteration iteratively constructs a tridiagonal matrix, the eigenvalues of which converge to the eigenvalues of `A`, as the iteration proceeds (most extreme first). Eigenvectors can also be computed. For small `k` and `kl` the approach is faster than computing the full symmetric eigendecomposition. The tridiagonal eigenproblems are handled using LAPACK.

The implementation is not optimal: in particular the inner tridiagonal problems could be handled more efficiently, and there would be some savings to be made by not always returning eigenvectors.

**Value**

A list with elements `values` (array of eigenvalues); `vectors` (matrix with eigenvectors in its columns); `iter` (number of iterations required).

**Author(s)**

ind <- c(1:6, (n-3):n)
range(er$values-um$values[ind]); range(abs(er$vectors)-abs(um$vectors[, ind]))
```

---

smooth.construct      *Constructor functions for smooth terms in a GAM*

---

## Description

Smooth terms in a GAM formula are turned into smooth specification objects of class `xx.smooth.spec` during processing of the formula. Each of these objects is converted to a smooth object using an appropriate `smooth.construct` function. New smooth classes can be added by writing a new `smooth.construct` method function and a corresponding `Predict.matrix` method function (see example code below).

In practice, `smooth.construct` is usually called via `smooth.construct2` and the wrapper function `smoothCon`, in order to handle by variables and centering constraints (see the `smoothCon` documentation if you need to handle these things directly, for a user defined smooth class).

## Usage

```
smooth.construct(object, data, knots)
smooth.construct2(object, data, knots)
```

## Arguments

**object** is a smooth specification object, generated by an `s` or `te` term in a GAM formula. Objects generated by `s` terms have class `xx.smooth.spec` where `xx` is given by the `bs` argument of `s` (this convention allows the user to add their own smoothers). If `object` is not class `tensor.smooth.spec` it will have the following elements:

**term** The names of the covariates for this smooth, in an array.

**bs.dim** Argument *k* of the *s* term generating the object. This is the dimension of the basis used to represent the term (or, arguably, 1 greater than the basis dimension for *cc* terms). `bs.dim < 0` indicates that the constructor should set this to the default value.

**fixed** TRUE if the term is to be unpenalized, otherwise FALSE.

**dim** the number covariates of which this smooth is a function.

**p.order** the order of the smoothness penalty or NA for autoselection of this. This is argument *m* of the *s* term that generated `object`.

**by** the name of any *by* variable to multiply this term as supplied as an argument to *s*. "NA" if there is no such term.

**label** A suitable label for use with this term.

**xt** An object containing information that may be needed for basis setup (used, e.g. by "tp" smooths to pass optional information on big dataset handling).

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides *sp* argument to [gam](#).

If `object` is of class `tensor.smooth.spec` then it was generated by a *te* term in the GAM formula, and specifies a smooth of several variables with a basis generated as a tensor product of lower dimensional bases. In this case the object will be different and will have the following elements:

**margin** is a list of smooth specification objects of the type listed above, defining the bases which have their tensor product formed in order to construct this term.

**term** is the array of names of the covariates that are arguments of the smooth.

**by** is the name of any *by* variable, or "NA".

**fx** is an array, the elements of which indicate whether (TRUE) any of the margins in the tensor product should be unpenalized.

**label** A suitable label for use with this term.

**dim** is the number of covariates of which this smooth is a function.

**mp** TRUE if multiple penalties are to be used.

**np** TRUE if 1-D marginal smooths are to be re-parameterized in terms of function values.

**id** Any identity associated with this term — used for linking bases and smoothing parameters. NULL by default, indicating no linkage.

**sp** Smoothing parameters for the term. Any negative are estimated, otherwise they are fixed at the supplied value. Unless NULL (default), over-rides *sp* argument to [gam](#).

**data** For `smooth.construct` a data frame or list containing the evaluation of the elements of `object$term`, with names given by `object$term`. The last entry will be the *by* variable, if `object$by` is not "NA". For `smooth.construct2` data need only be an object within which `object$term` can be evaluated, the variables can be in any order, and there can be irrelevant variables present as well.

**knots** an optional data frame or list containing the knots relating to `object$term`. If it is NULL then the knot locations are generated automatically. The structure of `knots` should be as for `data`, depending on whether `smooth.construct` or `smooth.construct2` is used.

## Details

There are built in methods for objects with the following classes: `tp.smooth.spec` (thin plate regression splines: see [tprs](#)); `ts.smooth.spec` (thin plate regression splines with shrinkage-to-zero); `cr.smooth.spec` (cubic regression splines: see [cubic.regression.spline](#)); `cs.smooth.spec` (cubic regression splines with shrinkage-to-zero); `cc.smooth.spec` (cyclic cubic regression splines); `ps.smooth.spec` (Eilers and Marx (1986) style P-splines: see [p.spline](#)); `cp.smooth.spec` (cyclic P-splines); `ad.smooth.spec` (adaptive smooths of 1 or 2 variables: see [adaptive.smooth](#)); `re.smooth.spec` (simple random effect terms); `mrf.smooth.spec` (Markov random field smoothers for smoothing over discrete districts); `tensor.smooth.spec` (tensor product smooths).

There is an implicit assumption that the basis only depends on the knots and/or the set of unique covariate combinations; i.e. that the basis is the same whether generated from the full set of covariates, or just the unique combinations of covariates.

Plotting of smooths is handled by plot methods for smooth objects. A default `mgcv.smooth` method is used if there is no more specific method available. Plot methods can be added for specific smooth classes, see source code for `mgcv::plot.sos.smooth`, `mgcv::plot.random.effect`, `mgcv::plot.mgcv.smooth` for example code.

## Value

The input argument `object`, assigned a new class to indicate what type of smooth it is and with at least the following items added:

<code>X</code>	The model matrix from this term. This may have an "offset" attribute: a vector of length <code>nrow(X)</code> containing any contribution of the smooth to the model offset term. <code>by</code> variables do not need to be dealt with here, but if they are then an item <code>by.done</code> must be added to the <code>object</code> .
<code>S</code>	A list of positive semi-definite penalty matrices that apply to this term. The list will be empty if the term is to be left un-penalized.
<code>rank</code>	An array giving the ranks of the penalties.
<code>null.space.dim</code>	The dimension of the penalty null space (before centering).

The following items may be added:

<code>C</code>	The matrix defining any identifiability constraints on the term, for use when fitting. If this is <code>NULL</code> then <code>smoothCon</code> will add an identifiability constraint that each term should sum to zero over the covariate values. Set to a zero row matrix if no constraints are required. If a supplied <code>C</code> has an attribute "always.apply" then it is never ignored, even if any <code>by</code> variables of a smooth imply that no constraint is actually needed. Code for creating <code>C</code> should check whether the specification object already contains a zero row matrix, and leave this unchanged if it is (since this signifies no constraint should be produced).
<code>Cp</code>	An optional matrix supplying alternative identifiability constraints for use when predicting. By default the fitting constraints are used. This option is useful when some sort of simple sparse constraint is required for fitting, but the usual sum-to-zero constraint is required for prediction so that, e.g. the CIs for model components are as narrow as possible.
<code>no.rescale</code>	if this is non- <code>NULL</code> then the penalty coefficient matrix of the smooth will not be rescaled for enhanced numerical stability (rescaling is the default, because

	<code>gamm</code> requires it). Turning off rescaling is useful if the values of the smoothing parameters should be interpretable in a model, for example because they are inverse variance components.
<code>df</code>	the degrees of freedom associated with this term (when unpenalized and unconstrained). If this is null then <code>smoothCon</code> will set it to the basis dimension. <code>smoothCon</code> will reduce this by the number of constraints.
<code>te.ok</code>	0 if this term should not be used as a tensor product marginal, 1 if it can be used and plotted, and 2 if it can be used but not plotted. Set to 1 if NULL.
<code>plot.me</code>	Set to FALSE if this smooth should not be plotted by <code>plot.gam</code> . Set to TRUE if NULL.
<code>side.constrain</code>	Set to FALSE to ensure that the smooth is never subject to side constraints as a result of nesting.
<code>L</code>	smooths may depend on fewer ‘underlying’ smoothing parameters than there are elements of <code>S</code> . In this case <code>L</code> is the matrix mapping the vector of underlying log smoothing parameters to the vector of logs of the smoothing parameters actually multiplying the <code>S[[i]]</code> . <code>L=NULL</code> signifies that there is one smoothing parameter per <code>S[[i]]</code> .

Usually the returned object will also include extra information required to define the basis, and used by `Predict.matrix` methods to make predictions using the basis. See the `Details` section for links to the information included for the built in smooth classes.

`tensor.smooth` returned objects will additionally have each element of the `margin` list updated in the same way. `tensor.smooths` also have a list, `XP`, containing re-parameterization matrices for any 1-D marginal terms re-parameterized in terms of function values. This list will have NULL entries for marginal smooths that are not re-parameterized, and is only long enough to reach the last re-parameterized marginal in the list.

## WARNING

User defined smooth objects should avoid having attributes names `"qrc"` or `"nCons"` as these are used internally to provide constraint free parameterizations.

smooth.construct.ad.smooth.spec

Adaptive smooths in GAMs

---

## Description

`gam` can use adaptive smooths of one or two variables, specified via terms like `s(...,bs="ad",...)`. (`gamm` can not use such terms — check out package `AdaptFit` if this is a problem.) The basis for such a term is a (tensor product of) p-spline(s) or cubic regression spline(s). Discrete P-spline type penalties are applied directly to the coefficients of the basis, but the penalties themselves have a basis representation, allowing the strength of the penalty to vary with the covariates. The coefficients of the penalty basis are the smoothing parameters.

When invoking an adaptive smoother the `k` argument specifies the dimension of the smoothing basis (default 40 in 1D, 15 in 2D), while the `m` argument specifies the dimension of the penalty basis (default 5 in 1D, 3 in 2D). For an adaptive smooth of two variables `k` is taken as the dimension of both marginal bases: different marginal basis dimensions can be specified by making `k` a two element vector. Similarly, in the two dimensional case `m` is the dimension of both marginal bases for the penalties, unless it is a two element vector, which specifies different basis dimensions for each marginal (If the penalty basis is based on a thin plate spline then `m` specifies its dimension directly).

By default, P-splines are used for the smoothing and penalty bases, but this can be modified by supplying a list as argument `xt` with a character vector `xt$bs` specifying the smoothing basis type. Only "ps", "cp", "cc" and "cr" may be used for the smoothing basis. The penalty basis is always a B-spline, or a cyclic B-spline for cyclic bases.

The total number of smoothing parameters to be estimated for the term will be the dimension of the penalty basis. Bear in mind that adaptive smoothing places quite severe demands on the data. For example, setting `m=10` for a univariate smooth of 200 data is rather like estimating 10 smoothing parameters, each from a data series of length 20. The problem is particularly serious for smooths of 2 variables, where the number of smoothing parameters required to get reasonable flexibility in the penalty can grow rather fast, but it often requires a very large smoothing basis dimension to make good use of this flexibility. In short, adaptive smooths should be used sparingly and with care.

In practice it is often as effective to simply transform the smoothing covariate as it is to use an adaptive smooth.

### Usage

```
## S3 method for class 'ad.smooth.spec'
smooth.construct(object, data, knots)
```

### Arguments

object	a smooth specification object, usually generated by a term <code>s(...,bs="ad",...)</code>
data	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
knots	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code>

### Details

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use [smooth.construct2](#).

This class can not be used as a marginal basis in a tensor product smooth, nor by `gamm`.

### Value

An object of class `"pspline.smooth"` in the 1D case or `"tensor.smooth"` in the 2D case.

smooth.construct.cr.smooth.spec

*Penalized Cubic regression splines in GAMs*

---

## Description

`gam` can use univariate penalized cubic regression spline smooths, specified via terms like `s(x,bs="cr")`. `s(x,bs="cs")` specifies a penalized cubic regression spline which has had its penalty modified to shrink towards zero at high enough smoothing parameters (as the smoothing parameter goes to infinity a normal cubic spline tends to a straight line.) `s(x,bs="cc")` specifies a cyclic penalized cubic regression spline smooth.

‘Cardinal’ spline bases are used: Wood (2006) sections 4.1.2 and 4.1.3 gives full details. These bases have very low setup costs. For a given basis dimension,  $k$ , they typically perform a little less well than thin plate regression splines, but a little better than  $p$ -splines. See [te](#) to use these bases in tensor product smooths of several variables.

Default  $k$  is 10.

## Usage

```
## S3 method for class 'cr.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cc.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

object	a smooth specification object, usually generated by a term <code>s(..., bs="cr", ...)</code> , <code>s(..., bs="cs", ...)</code> or <code>s(..., bs="cc", ...)</code>
data	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
knots	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details.

## Details

The constructor is not normally called directly, but is rather used internally by [gam](#). To use for basis setup it is recommended to use `smooth.construct2`.

If they are not supplied then the knots of the spline are placed evenly throughout the covariate values to which the term refers: For example, if fitting 101 data with an 11 knot spline of  $x$  then there would be a knot at every 10th (ordered)  $x$  value. The parameterization used represents the spline in terms of its values at the knots. The values at neighbouring knots are connected by sections of cubic polynomial constrained to be continuous up to and including second derivative at the knots. The resulting curve is a natural cubic spline through the values at the knots (given two extra conditions specifying that the second derivative of the curve should be zero at the two end knots).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its 2 zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

Note that the cyclic smoother will wrap at the smallest and largest covariate values, unless knots are supplied. If only two knots are supplied then they are taken as the end points of the smoother (provided all the data lie between them), and the remaining knots are generated automatically.

The cyclic smooth is not subject to the condition that second derivatives go to zero at the first and last knots.

**Value**

An object of class "cr.smooth" "cs.smooth" or "cyclic.smooth". In addition to the usual elements of a smooth class documented under [smooth.construct](#), this object will contain:

xp	giving the knot locations used to generate the basis.
BD	class "cyclic.smooth" objects include matrix BD which transforms function values at the knots to second derivatives at the knots.

smooth.construct.ds.smooth.spec

*Low rank Duchon 1977 splines*

---

**Description**

Thin plate spline smoothers are a special case of the isotropic splines discussed in Duchon (1977). A subset of this more general class can be invoked by terms like `s(x, z, bs="ds", m=c(1, .5))` in a `gam` model formula. In the notation of Duchon (1977) `m` is given by `m[1]` (default value 2), while `s` is given by `m[2]` (default value 0).

Duchon's (1977) construction generalizes the usual thin plate spline penalty as follows. The usual TPS penalty is given by the integral of the squared Euclidian norm of a vector of mixed partial  $m$ th order derivatives of the function w.r.t. its arguments. Duchon re-expresses this penalty in the Fourier domain, and then weights the squared norm in the integral by the Euclidean norm of the fourier frequencies, raised to the power  $2s$ .  $s$  is a user selected constant taking integer values divided by 2. If  $d$  is the number of arguments of the smooth, then it is required that  $-d/2 < s < d/2$ . To obtain continuous functions we further require that  $m + s > d/2$ . If  $s=0$  then the usual thin plate spline is recovered.

The construction is amenable to exactly the low rank approximation method given in Wood (2003) to thin plate splines, with similar optimality properties, so this approach to low rank smoothing is used here. For large datasets the same subsampling approach as is used in the `tprs` case is employed here to reduce computational costs.

These smoothers allow the use of lower orders of derivative in the penalty than conventional thin plate splines, while still yielding continuous functions. For example, we can set  $m = 1$  and  $s = d/2 - .5$  in order to use first derivative penalization for any  $d$  (which has the advantage that the dimension of the null space of unpenalized functions is only  $d+1$ ).

### Usage

```
## S3 method for class 'ds.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'duchon.spline'
Predict.matrix(object, data)
```

### Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(..., bs="ds", ...)</code> .
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code>

### Details

The default basis dimension for this class is  $k=M+k_{\text{def}}$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k_{\text{def}}$  is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification `object` will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R's RNG.

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension, `k`. This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension, `k`. For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

## Value

An object of class `"duchon.spline"`. In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

<code>shift</code>	A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otehrwise occur in the penalty null space basis of the term.
<code>Xu</code>	A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
<code>UZ</code>	The matrix mapping the smoother parameters back to the parameters of a full Duchon spline.
<code>null.space.dimension</code>	The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.

*Factor smooth interactions in GAMs*

---

## Description

Simple factor smooth interactions, which are efficient when used with [gamm](#). This smooth class allows a separate smooth for each level of a factor, with the same smoothing parameter for all smooths. It is an alternative to using factor by variables.

See the discussion of by variables in [gam.models](#) for more general alternatives for factor smooth interactions (including interactions of tensor product smooths with factors).

## Usage

```
## S3 method for class 'fs.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'fs.interaction'
Predict.matrix(object, data)
```

## Arguments

object	For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x, ..., bs="fs", )</code> . For the <code>predict.Matrix</code> method an object of class <code>"fs.interaction"</code> produced by the <code>smooth.construct</code> method.
data	a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> .
knots	a list containing any knots supplied for smooth basis setup.

## Details

This class produces a smooth for each level of a single factor variable. Within a [gam](#) formula this is done with something like `s(x, fac, bs="fs")`, which is almost equivalent to `s(x, by=fac, id=1)` (with the `gam` argument `select=TRUE`). The terms are fully penalized, with separate penalties on each null space component: for this reason they are not centred (no sum-to-zero constraint).

The class is particularly useful for use with [gamm](#), where estimation efficiently exploits the nesting of the smooth within the factor. Note however that: i) [gamm](#) only allows one conditioning factor for smooths, so `s(x) + s(z, fac, bs="fs") + s(v, fac, bs="fs")` is OK, but `s(x) + s(z, fac1, bs="fs") + s(v, fac2, bs="fs")` is not; ii) all additional random effects and correlation structures will be treated as nested within the factor of the smooth factor interaction.

Note that [gamm4](#) from the [gamm4](#) package suffers from none of the restrictions that apply to [gamm](#), and `"fs"` terms can be used without side-effects.

Any singly penalized basis can be used to smooth at each factor level. The default is "tp", but alternatives can be supplied in the `xt` argument of `s` (e.g. `s(x, fac, bs="fs", xt="cr")` or `s(x, fac, bs="fs", xt=list(bs="cr"))`). The `k` argument to `s(..., bs="fs")` refers to the basis dimension to use for each level of the factor variable.

Note one computational bottleneck: currently `gamm` (or `gamm4`) will produce the full posterior covariance matrix for the smooths, including the smooths at each level of the factor. This matrix can get large and computationally costly if there are more than a few hundred levels of the factor. Even at one or two hundred levels, care should be taken to keep down `k`.

The plot method for this class has two schemes. `scheme==0` is in colour, while `scheme==1` is black and white.

## Value

An object of class `"fs.interaction"` or a matrix mapping the coefficients of the factor smooth interaction to the smooths themselves.

smooth.construct.gp.smooth.spec
```

*Low rank Gaussian process smooths*

---

## Description

Gaussian process/kriging models based on simple covariance functions can be written in a very similar form to thin plate and Duchon spline models (e.g. Handcock, Meier, Nychka, 1994), and low rank versions produced by the eigen approximation method of Wood (2003). Kammann and Wand (2003) suggest a particularly simple form of the Matern covariance function with only a single smoothing parameter to estimate, and this class implements this and other similar models.

Usually invoked by an `s(..., bs="gp")` term in a `gam` formula. Argument `m` selects the covariance function, sets the range parameter and any power parameter. If `m` is not supplied then it defaults to `NA` and the covariance function suggested by Kammann and Wand (2003) along with their suggested range parameter is used. Otherwise `m[1]` between 1 and 5 selects the correlation function from respectively, spherical, power exponential, and Matern with  $\kappa = 1.5, 2.5$  or  $3.5$ . `m[2]` if present specifies the range parameter, with non-positive or absent indicating that the Kammann and Wand estimate should be used. `m[3]` can be used to specify the power for the power exponential which otherwise defaults to 1.

## Usage

```
## S3 method for class 'gp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'gp.smooth'
Predict.matrix(object, data)
```

## Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(..., bs="ms", ...)</code> .
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code>

## Details

Let  $\rho > 0$  be the range parameter,  $0 < \kappa \leq 2$  and  $d$  denote the distance between two points. Then the correlation functions indexed by `m[1]` are:

1.  $1 - 1.5d/\rho + 0.5(d/\rho)^3$  if  $d \leq \rho$  and 0 otherwise.
2.  $\exp(-(d/\rho)^\kappa)$ .
3.  $\exp(-d/\rho)(1 + d/\rho)$ .
4.  $\exp(-d/\rho)(1 + d/\rho + (d/\rho)^2/3)$ .
5.  $\exp(-d/\rho)(1 + d/\rho + 2(d/\rho)^2/5 + (d/\rho)^3/15)$ .

See Fahrmeir et al. (2013) section 8.1.6, for example.

The default basis dimension for this class is  $k=M+k.\text{def}$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k.\text{def}$  is 10 for dimension 1, 30 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification `object` will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a reduced rank eigen approximation to the full basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing). Note that the random sampling will not effect the state of R's RNG.

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the spline basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

## Value

An object of class `"gp.smooth"`. In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

<code>shift</code>	A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
<code>Xu</code>	A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
<code>UZ</code>	The matrix mapping the smoother parameters back to the parameters of a full GP smooth.
<code>null.space.dimension</code>	The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.
<code>gp.defn</code>	the type, range parameter and power parameter defining the correlation function.

*Markov Random Field Smooths*

---

## Description

For data observed over discrete spatial units, a simple Markov random field smoother is sometimes appropriate. These functions provide such a smoother class for `mgcv`. See details for how to deal with regions with missing data.

## Usage

```
## S3 method for class 'mrf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'mrf.smooth'
Predict.matrix(object, data)
```

## Arguments

<code>object</code>	For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x, ..., bs="mrf", xt=list(polys=foo))</code> . <code>x</code> is a factor variable giving labels for geographic districts, and the <code>xt</code> argument is obligatory: see details. For the <code>Predict.Matrix</code> method an object of class <code>"mrf.smooth"</code> produced by the <code>smooth.construct</code> method.
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	If there are more geographic areas than data were observed for, then this argument is used to provide the labels for all the areas (observed and unobserved).

## Details

A Markov random field smooth over a set of discrete areas is defined using a set of area labels, and a neighbourhood structure for the areas. The covariate of the smooth is the vector of area labels corresponding to each observation. This covariate should be a factor, or capable of being coerced to a factor.

The neighbourhood structure is supplied in the `xt` argument to `s`. This must contain at least one of the elements `polys`, `nb` or `penalty`.

**polys** contains the polygons defining the geographic areas. It is a list with as many elements as there are geographic areas. `names(polys)` must correspond to the levels of the argument of the smooth, in any order (i.e. it gives the area labels). `polys[[i]]` is a 2 column matrix the rows of which specify the vertices of the polygon(s) defining the boundary of the *i*th area. A boundary may be made up of several closed loops: these must be separated by NA rows. A polygon within another is treated as a hole. The first polygon in any `polys[[i]]` should not be a hole. An example of the structure is provided by `columb.polys` (which contains an artificial hole in its second element, for illustration). Any list elements with duplicate names are combined into a single NA separated matrix.

Plotting of the smooth is not possible without a `polys` object.

If `polys` is the only element of `xt` provided, then the neighbourhood structure is computed from it automatically. To count as neighbours, polygons must exactly share one of more vertices.

**nb** is a named list defining the neighbourhood structure. `names(nb)` must correspond to the levels of the covariate of the smooth (i.e. the area labels), but can be in any order. `nb[[i]]` is a vector indexing the neighbours of the *i*th area. All indices are relative to `nb` itself, but can be translated using `names(nb)`.

If no `penalty` is provided then it is computed automatically from this list. The *i*th row of the penalty matrix will be zero everywhere, except in the *i*th column, which will contain the number of neighbours of the *i*th geographic area, and the columns corresponding to those geographic neighbours, which will each contain -1.

**penalty** if this is supplied, then it is used as the penalty matrix. It should be positive semi-definite. Its row and column names should correspond to the levels of the covariate.

If no basis dimension is supplied then the constructor produces a full rank MRF, with a coefficient for each geographic area. Otherwise a low rank approximation is obtained based on truncation of the parameterization given in Wood (2006) Section 4.10.4.

Note that smooths of this class have a built in plot method, and that the utility function `in.out` can be useful for working with discrete area data. The plot method has two schemes, `scheme==0` is colour, `scheme==1` is grey scale.

The situation in which there are areas with no data requires special handling. You should set `drop.unused.levels=FALSE` in the model fitting function, `gam`, `bam` or `gamm`, having first ensured that any fixed effect factors do not contain unobserved levels. Also make sure that the basis dimension is set to ensure that the total number of coefficients is less than the number of observations.

## Value

An object of class `"mrf.smooth"` or a matrix mapping the coefficients of the MRF smooth to the predictions for the areas listed in `data`.

---

smooth.construct.ps.smooth.spec  
*P-splines in GAMs*

---

## Description

`gam` can use univariate P-splines as proposed by Eilers and Marx (1996), specified via terms like `s(x, bs="ps")`. These terms use B-spline bases penalized by discrete penalties applied directly to the basis coefficients. Cyclic P-splines are specified by model terms like `s(x, bs="cp", ...)`. These bases can be used in tensor product smooths (see [te](#)).

The advantage of P-splines is the flexible way that penalty and basis order can be mixed. This often provides a useful way of ‘taming’ an otherwise poorly behave smooth. However, in regular use, splines with derivative based penalties (e.g. "tp" or "cr" bases) tend to result in slightly better MSE performance, presumably because the good approximation theoretic properties of splines are rather closely connected to the use of derivative penalties.

## Usage

```
## S3 method for class 'ps.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'cp.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(x, bs="ps", ...)</code> or <code>s(x, bs="cp", ...)</code>
<code>data</code>	a list containing just the data (including any by variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The by variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details for further information.

## Details

A smooth term of the form `s(x, bs="ps", m=c(2, 3))` specifies a 2nd order P-spline basis (cubic spline), with a third order difference penalty (0th order is a ridge penalty) on the coefficients. If `m` is a single number then it is taken as the basis order and penalty order. The default is the ‘cubic spline like’ `m=c(2, 2)`.

The default basis dimension, `k`, is the larger of 10 and `m[1]+1` for a "ps" terms and the larger of 10 and `m[1]` for a "cp" term. `m[1]+1` and `m[1]` are the lower limits on basis dimension for the two types.

If knots are supplied, then the number of knots should be one more than the basis dimension (i.e. `k+1`) for a "cp" smooth. For the "ps" basis the number of supplied knots should be `k + m[1] + 2`, and the range of the middle `k-m[1]` knots should include all the covariate values. See example.

Alternatively, for both types of smooth, 2 knots can be supplied, denoting the lower and upper limits between which the spline can be evaluated (Don't make this range too wide, however, or you can end up with no information about some basis coefficients, because the corresponding basis functions

have a span that includes no data!). Note that P-splines don't make much sense with uneven knot spacing.

Linear extrapolation is used for prediction that requires extrapolation (i.e. prediction outside the range of the interior  $k-m[1]$  knots). Such extrapolation is not allowed in basis construction, but is when predicting.

### Value

An object of class "ps.smooth" or "cp.smooth". See [smooth.construct](#), for the elements that this object will contain.

smooth.construct.re.smooth.spec
```

*Simple random effects in GAMs*

---

## Description

`gam` can deal with simple independent random effects, by exploiting the link between smooths and random effects to treat random effects as smooths. `s(x, bs="re")` implements this. Such terms can have any number of predictors, which can be any mixture of numeric or factor variables. The terms produce a parametric interaction of the predictors, and penalize the corresponding coefficients with a multiple of the identity matrix, corresponding to an assumption of i.i.d. normality. See details.

## Usage

```
## S3 method for class 're.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'random.effect'
Predict.matrix(object, data)
```

## Arguments

<code>object</code>	For the <code>smooth.construct</code> method a smooth specification object, usually generated by a term <code>s(x, ..., bs="re", )</code> . For the <code>predict.Matrix</code> method an object of class <code>"random.effect"</code> produced by the <code>smooth.construct</code> method.
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	generically a list containing any knots supplied for basis setup — unused at present.

## Details

Exactly how the random effects are implemented is best seen by example. Consider the model term `s(x, z, bs="re")`. This will result in the model matrix component corresponding to  $\sim x:z-1$  being added to the model matrix for the whole model. The coefficients associated with the model matrix component are assumed i.i.d. normal, with unknown variance (to be estimated). This assumption is equivalent to an identity penalty matrix (i.e. a ridge penalty) on the coefficients. Because such a penalty is full rank, random effects terms do not require centering constraints.

If the nature of the random effect specification is not clear, consider a couple more examples: `s(x, bs="re")` results in `model.matrix(~x-1)` being appended to the overall model matrix, while `s(x, v, w, bs="re")` would result in `model.matrix(~x:v:w-1)` being appended to the model matrix. In both cases the corresponding model coefficients are assumed i.i.d. normal, and are hence subject to ridge penalties.

Note that smooth `ids` are not supported for random effect terms. Unlike most smooth terms, side conditions are never applied to random effect terms in the event of nesting (since they are identifiable without side conditions).

Random effects implemented in this way do not exploit the sparse structure of many random effects, and may therefore be relatively inefficient for models with large numbers of random effects, when

gamm4 or [gamm](#) may be better alternatives. Note also that [gam](#) will not support models with more coefficients than data.

The situation in which factor variable random effects intentionally have unobserved levels requires special handling. You should set `drop.unused.levels=FALSE` in the model fitting function, [gam](#), [bam](#) or [gamm](#), having first ensured that any fixed effect factors do not contain unobserved levels.

## Value

An object of class "random.effect" or a matrix mapping the coefficients of the random effect to the random effects themselves.

*Soap film smoother constructor*

---

## Description

Sets up basis functions and wiggleness penalties for soap film smoothers (Wood, Bravington and Hedley, 2008). Soap film smoothers are based on the idea of constructing a 2-D smooth as a film of soap connecting a smoothly varying closed boundary. Unless smoothing very heavily, the film is distorted towards the data. The smooths are designed not to smooth across boundary features (peninsulas, for example).

The `so` version sets up the full smooth. The `sf` version sets up just the boundary interpolating soap film, while the `sw` version sets up the wiggly component of a soap film (zero on the boundary). The latter two are useful for forming tensor products with soap films, and can be used with [gamm](#) and [gamm4](#). To use these to simply set up a basis, then call via the wrapper [smooth.construct2](#) or [smoothCon](#).

## Usage

```
## S3 method for class 'so.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sf.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sw.smooth.spec'
smooth.construct(object, data, knots)
```

## Arguments

<code>object</code>	A smooth specification object as produced by a <code>s(..., bs="so", xt=list(bnd=bnd, ...))</code> term in a gam formula. Note that the <code>xt</code> argument to <code>s</code> <i>must</i> be supplied, and should be a list, containing at least a boundary specification list (see details). <code>xt</code> may also contain various options controlling the boundary smooth (see details), and PDE solution grid. The dimension of the bases for boundary loops is specified via the <code>k</code> argument of <code>s</code> , either as a single number to be used for each boundary loop, or as a vector of different basis dimensions for the various boundary loops.
<code>data</code>	A list or data frame containing the arguments of the smooth.
<code>knots</code>	list or data frame with two named columns specifying the knot locations within the boundary. The column names should match the names of the arguments of the smooth. The number of knots defines the <i>interior</i> basis dimension (i.e. it is <i>not</i> supplied via argument <code>k</code> of <code>s</code> ).

## Details

For soap film smooths the following *must* be supplied:

- `k` the basis dimension for each boundary loop smooth.
- `xt$bnd` the boundary specification for the smooth.
- `knots` the locations of the interior knots for the smooth.

When used in a GAM then `k` and `xt` are supplied via `s` while `knots` are supplied in the `knots` argument of `gam`.

The `bnd` element of the `xt` list is a list of lists (or data frames), specifying the loops that define the boundary. Each boundary loop list must contain 2 columns giving the co-ordinates of points defining a boundary loop (when joined sequentially by line segments). Loops should not intersect (not checked). A point is deemed to be in the region of interest if it is interior to an odd number of boundary loops. Each boundary loop list may also contain a column `f` giving known boundary conditions on a loop.

The `bndSpec` element of `xt`, if non-NULL, should contain

- `bs` the type of cyclic smoothing basis to use: one of "cc" and "cp". If not "cc" then a cyclic p-spline is used, and argument `m` must be supplied.
- `knot.space` set to "even" to get even knot spacing with the "cc" basis.
- `m` 1 or 2 element array specifying order of "cp" basis and penalty.

Currently the code will not deal with more than one level of nesting of loops, or with separate loops without an outer enclosing loop: if there are known boundary conditions (identifiability constraints get awkward).

Note that the function `locator` provides a simple means for defining boundaries graphically, using something like `bnd <- as.data.frame(locator(type="l"))`, after producing a plot of the domain of interest (right click to stop). If the real boundary is very complicated, it is probably better to use a simpler smooth boundary enclosing the true boundary, which represents the major boundary features that you don't want to smooth across, but doesn't follow every tiny detail.

Model set up, and prediction, involves evaluating basis functions which are defined as the solution to PDEs. The PDEs are solved numerically on a grid using sparse matrix methods, with bilinear interpolation used to obtain values at any location within the smoothing domain. The dimension of the PDE solution grid can be controlled via element `nmax` (default 200) of the list supplied as argument `xt` of `s` in a `gam` formula: it gives the number of cells to use on the longest grid side.

A little theory: the soap film smooth  $f(x, y)$  is defined as the solution of

$$f_{xx} + f_{yy} = g$$

subject to the condition that  $f = s$ , on the boundary curve, where  $s$  is a smooth function (usually a cyclic penalized regression spline). The function  $g$  is defined as the solution of

$$g_{xx} + g_{yy} = 0$$

where  $g = 0$  on the boundary curve and  $g(x_k, y_k) = c_k$  at the 'knots' of the surface; the  $c_k$  are model coefficients.

In the simplest case, estimation of the coefficients of  $f$  (boundary coefficients plus  $c_k$ 's) is by minimization of

$$\|z - f\|^2 + \lambda_s J_s(s) + \lambda_f J_f(f)$$

where  $J_s$  is usually some cubic spline type wiggleness penalty on the boundary smooth and  $J_f$  is the integral of  $(f_{xx} + f_{yy})^2$  over the interior of the boundary. Both penalties can be expressed as quadratic forms in the model coefficients. The  $\lambda$ 's are smoothing parameters, selectable by GCV, REML, AIC, etc.  $z$  represents noisy observations of  $f$ .

## Value

A list with all the elements of `object` plus

<code>sd</code>	A list defining the PDE solution grid and domain boundary, and including the sparse LU factorization of the PDE coefficient matrix.
<code>x</code>	The model matrix: this will have an <code>"offset"</code> attribute, if there are any known boundary conditions.
<code>s</code>	List of smoothing penalty matrices (in smallest non-zero submatrix form).
<code>irng</code>	A vector of scaling factors that have been applied to the model matrix, to ensure nice conditioning.

In addition there are all the elements usually added by `smooth.construct` methods.

## WARNINGS

Soap film smooths are quite specialized, and require more setup than most smoothers (e.g. you have to supply the boundary and the interior knots, plus the boundary smooth basis dimension(s)). It is worth looking at the reference.

*Splines on the sphere*

---

## Description

`gam` can use isotropic smooths on the sphere, via terms like `s(la, lo, bs="sos", m=2, k=100)`. There must be exactly 2 arguments to such a smooth. The first is taken to be latitude (in degrees) and the second longitude (in degrees). `m` (default 0) is an integer in the range -1 to 4 determining the order of the penalty used. For  $m > 0$ ,  $(m+2)/2$  is the penalty order, with  $m=2$  equivalent to the usual second derivative penalty.  $m=0$  signals to use the 2nd order spline on the sphere, computed by Wendelberger's (1981) method.  $m = -1$  results in a [Duchon.spline](#) being used (with  $m=2$  and  $s=1/2$ ), following an unpublished suggestion of Jean Duchon.

`k` (default 50) is the basis dimension.

## Usage

```

## S3 method for class 'sos.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'sos.smooth'
Predict.matrix(object, data)

```

## Arguments

<code>object</code>	a smooth specification object, usually generated by a term <code>s(..., bs="sos", ...)</code> .
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code>

## Details

For  $m > 0$ , the smooths implemented here are based on the pseudosplines on the sphere of Wahba (1981) (there is a correction of table 1 in 1982, but the correction has a misprint in the definition of  $A$  — the  $A$  given in the 1981 paper is correct). For  $m = 0$  (default) then a second order spline on the sphere is used which is the analogue of a second order thin plate spline in 2D: the computation is based on Chapter 4 of Wendelberger, 1981. Optimal low rank approximations are obtained using exactly the approach given in Wood (2003). For  $m = -1$  a smooth of the general type discussed in Duchon (1977) is used: the sphere is embedded in a 3D Euclidean space, but smoothing employs a penalty based on second derivatives (so that locally as the smoothing parameter tends to zero we recover a "normal" thin plate spline on the tangent space). This is an unpublished suggestion of Jean Duchon.

Note that the null space of the penalty is always the space of constant functions on the sphere, whatever the order of penalty.

This class has a plot method, with 3 schemes. `scheme==0` plots one hemisphere of the sphere, projected onto a circle. The plotting sphere has the north pole at the top, and the 0 meridian running down the middle of the plot, and towards the viewer. The smoothing sphere is rotated within the plotting sphere, by specifying the location of its pole in the co-ordinates of the viewing sphere. `theta, phi` give the longitude and latitude of the smoothing sphere pole within the plotting sphere (in plotting sphere co-ordinates). (You can visualize the smoothing sphere as a globe, free to rotate within the fixed transparent plotting sphere.) The value of the smooth is shown by a heat map overlaid with a contour plot. `lat, lon` gridlines are also plotted.

`scheme==1` is as `scheme==0`, but in black and white, without the image plot. `scheme>1` calls the default plotting method with `scheme` decremented by 2.

## Value

An object of class "`sos.smooth`". In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

<code>Xu</code>	A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).
<code>UZ</code>	The matrix mapping the parameters of the reduced rank spline back to the parameters of a full spline.

---

```
smooth.construct.t2.smooth.spec  
Tensor product smoothing constructor
```

---

## Description

A special `smooth.construct` method function for creating tensor product smooths from any combination of single penalty marginal smooths, using the construction of Wood, Scheipl and Faraway (2013).

## Usage

```
## S3 method for class 't2.smooth.spec'  
smooth.construct(object, data, knots)
```

## Arguments

<code>object</code>	a smooth specification object of class <code>t2.smooth.spec</code> , usually generated by a term like <code>t2(x, z)</code> in a <a href="#">gam</a> model formula
<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code> . See details for further information.

## Details

Tensor product smooths are smooths of several variables which allow the degree of smoothing to be different with respect to different variables. They are useful as smooth interaction terms, as they are invariant to linear rescaling of the covariates, which means, for example, that they are insensitive to the measurement units of the different covariates. They are also useful whenever isotropic smoothing is inappropriate. See [t2](#), [te](#), [smooth.construct](#) and [smooth.terms](#). The construction employed here produces tensor smooths for which the smoothing penalties are non-overlapping portions of the identity matrix. This makes their estimation by mixed modelling software rather easy.

## Value

An object of class `"t2.smooth"`.

## Author(s)

---

smooth.construct.tp.smooth.spec*Penalized thin plate regression splines in GAMs*

---

**Description**

`gam` can use isotropic smooths of any number of variables, specified via terms like `s(x, z, bs="tp", m=3)` (or just `s(x, z)` as this is the default basis). These terms are based on thin plate regression splines. `m` specifies the order of the derivatives in the thin plate spline penalty. If `m` is a vector of length 2 and the second element is zero, then the penalty null space of the smooth is not included in the smooth: this is useful if you need to test whether a smooth could be replaced by a linear term, for example.

Thin plate regression splines are constructed by starting with the basis and penalty for a full thin plate spline and then truncating this basis in an optimal manner, to obtain a low rank smoother. Details are given in Wood (2003). One key advantage of the approach is that it avoids the knot placement problems of conventional regression spline modelling, but it also has the advantage that smooths of lower rank are nested within smooths of higher rank, so that it is legitimate to use conventional hypothesis testing methods to compare models based on pure regression splines. Note that the basis truncation does not change the meaning of the thin plate spline penalty (it penalizes exactly what it would have penalized for a full thin plate spline).

The t.p.r.s. basis and penalties can become expensive to calculate for large datasets. For this reason the default behaviour is to randomly subsample `max.knots` unique data locations if there are more than `max.knots` such, and to use the sub-sample for basis construction. The sampling is always done with the same random seed to ensure repeatability (does not reset R RNG). `max.knots` is 2000, by default. Both seed and `max.knots` can be modified using the `xt` argument to `s`. Alternatively the user can supply knots from which to construct a basis.

The "ts" smooths are t.p.r.s. with the penalty modified so that the term is shrunk to zero for high enough smoothing parameter, rather than being shrunk towards a function in the penalty null space (see details).

**Usage**

```
## S3 method for class 'tp.smooth.spec'
smooth.construct(object, data, knots)
## S3 method for class 'ts.smooth.spec'
smooth.construct(object, data, knots)
```

**Arguments**

`object` a smooth specification object, usually generated by a term `s(..., bs="tp", ...)` or `s(..., bs="ts", ...)`

<code>data</code>	a list containing just the data (including any <code>by</code> variable) required by this term, with names corresponding to <code>object\$term</code> (and <code>object\$by</code> ). The <code>by</code> variable is the last element.
<code>knots</code>	a list containing any knots supplied for basis setup — in same order and with same names as <code>data</code> . Can be <code>NULL</code>

## Details

The default basis dimension for this class is  $k = M + k_{\text{def}}$  where  $M$  is the null space dimension (dimension of unpenalized function space) and  $k_{\text{def}}$  is 8 for dimension 1, 27 for dimension 2 and 100 for higher dimensions. This is essentially arbitrary, and should be checked, but as with all penalized regression smoothers, results are statistically insensitive to the exact choice, provided it is not so small that it forces oversmoothing (the smoother's degrees of freedom are controlled primarily by its smoothing parameter).

The default is to set  $m$  (the order of derivative in the thin plate spline penalty) to the smallest value satisfying  $2m > d + 1$  where  $d$  is the number of covariates of the term: this yields 'visually smooth' functions. In any case  $2m > d$  must be satisfied.

The constructor is not normally called directly, but is rather used internally by `gam`. To use for basis setup it is recommended to use `smooth.construct2`.

For these classes the specification `object` will contain information on how to handle large datasets in their `xt` field. The default is to randomly subsample 2000 'knots' from which to produce a `tp` basis, if the number of unique predictor variable combinations in excess of 2000. The default can be modified via the `xt` argument to `s`. This is supplied as a list with elements `max.knots` and `seed` containing a number to use in place of 2000, and the random number seed to use (either can be missing).

For these bases `knots` has two uses. Firstly, as mentioned already, for large datasets the calculation of the `tp` basis can be time-consuming. The user can retain most of the advantages of the `t.p.r.s.` approach by supplying a reduced set of covariate values from which to obtain the basis - typically the number of covariate values used will be substantially smaller than the number of data, and substantially larger than the basis dimension,  $k$ . This approach is the one taken automatically if the number of unique covariate values (combinations) exceeds `max.knots`. The second possibility is to avoid the eigen-decomposition used to find the `t.p.r.s.` basis altogether and simply use the basis implied by the chosen knots: this will happen if the number of knots supplied matches the basis dimension,  $k$ . For a given basis dimension the second option is faster, but gives poorer results (and the user must be quite careful in choosing knot locations).

The shrinkage version of the smooth, eigen-decomposes the wiggleness penalty matrix, and sets its zero eigenvalues to small multiples of the smallest strictly positive eigenvalue. The penalty is then set to the matrix with eigenvectors corresponding to those of the original penalty, but eigenvalues set to the perturbed versions. This penalty matrix has full rank and shrinks the curve to zero at high enough smoothing parameters.

## Value

An object of class `"tp.r.s.smooth"` or `"ts.smooth"`. In addition to the usual elements of a smooth class documented under `smooth.construct`, this object will contain:

<code>shift</code>	A record of the shift applied to each covariate in order to center it around zero and avoid any co-linearity problems that might otherwise occur in the penalty null space basis of the term.
<code>Xu</code>	A matrix of the unique covariate combinations for this smooth (the basis is constructed by first stripping out duplicate locations).

UZ                    The matrix mapping the t.p.r.s. parameters back to the parameters of a full thin plate spline.

null.space.dimension                    The dimension of the space of functions that have zero wiggleness according to the wiggleness penalty for this term.

smooth.terms

*Smooth terms in GAM*

---

### Description

Smooth terms are specified in a [gam](#) formula using [s](#), [te](#), [ti](#) and [t2](#) terms. Various smooth classes are available, for different modelling tasks, and users can add smooth classes (see [user.defined.smooth](#)). What defines a smooth class is the basis used to represent the smooth function and quadratic penalty (or multiple penalties) used to penalize the basis coefficients in order to control the degree of smoothness. Smooth classes are invoked directly by [s](#) terms, or as building blocks for tensor product smoothing via [te](#), [ti](#) or [t2](#) terms (only smooth classes with single penalties can be used in tensor products). The smooths built into the [mgcv](#) package are all based one way or another on low rank versions of splines. For the full rank versions see Wahba (1990).

Note that smooths can be used rather flexibly in [gam](#) models. In particular the linear predictor of the GAM can depend on (a discrete approximation to) any linear functional of a smooth term, using [by](#) variables and the ‘summation convention’ explained in [linear.functional.terms](#).

The single penalty built in smooth classes are summarized as follows

**Thin plate regression splines** [bs="tp"](#). These are low rank isotropic smoothers of any number of covariates. By isotropic is meant that rotation of the covariate co-ordinate system will not change the result of smoothing. By low rank is meant that they have far fewer coefficients than there are data to smooth. They are reduced rank versions of the thin plate splines and use the thin plate spline penalty. They are the default smooth for [s](#) terms because there is a defined sense in which they are the optimal smoother of any given basis dimension/rank (Wood, 2003). Thin plate regression splines do not have ‘knots’ (at least not in any conventional sense): a truncated eigen-decomposition is used to achieve the rank reduction. See [tprs](#) for further details.

[bs="ts"](#) is as ["tp"](#) but with a modification to the smoothing penalty, so that the null space is also penalized slightly and the whole term can therefore be shrunk to zero.

**Duchon splines** `bs="ds"`. These generalize thin plate splines. In particular, for any given number of covariates they allow lower orders of derivative in the penalty than thin plate splines (and hence a smaller null space). See [Duchon.spline](#) for further details.

**Cubic regression splines** `bs="cr"`. These have a cubic spline basis defined by a modest sized set of knots spread evenly through the covariate values. They are penalized by the conventional integrated square second derivative cubic spline penalty. For details see [cubic.regression.spline](#) and e.g. Wood (2006a).

`bs="cs"` specifies a shrinkage version of `"cr"`.

`bs="cc"` specifies a cyclic cubic regression splines (see [cyclic.cubic.spline](#)). i.e. a penalized cubic regression splines whose ends match, up to second derivative.

**Splines on the sphere** `bs="sos"`. These are two dimensional splines on a sphere. Arguments are latitude and longitude, and they are the analogue of thin plate splines for the sphere. Useful for data sampled over a large portion of the globe, when isotropy is appropriate. See [Spherical.Spline](#) for details.

**P-splines** `bs="ps"`. These are P-splines as proposed by Eilers and Marx (1996). They combine a B-spline basis, with a discrete penalty on the basis coefficients, and any sane combination of penalty and basis order is allowed. Although this penalty has no exact interpretation in terms of function shape, in the way that the derivative penalties do, P-splines perform almost as well as conventional splines in many standard applications, and can perform better in particular cases where it is advantageous to mix different orders of basis and penalty.

`bs="cp"` gives a cyclic version of a P-spline (see [cyclic.p.spline](#)).

**Random effects** `bs="re"`. These are parametric terms penalized by a ridge penalty (i.e. the identity matrix). When such a smooth has multiple arguments then it represents the parametric interaction of these arguments, with the coefficients penalized by a ridge penalty. The ridge penalty is equivalent to an assumption that the coefficients are i.i.d. normal random effects. See [smooth.construct.re.smooth.spec](#).

**Markov Random Fields** `bs="mrf"`. These are popular when space is split up into discrete contiguous geographic units (districts of a town, for example). In this case a simple smoothing penalty is constructed based on the neighbourhood structure of the geographic units. See [mrf](#) for details and an example.

**Gaussian process smooths** `bs="gp"`. Gaussian process models with a variety of simple correlation functions can be represented as smooths. See [gp.smooth](#) for details.

**Soap film smooths** `bs="so"` (actually not single penaltied, but `bs="sw"` and `bs="sf"` allows splitting into single penalty components for use in tensor product smoothing). These are finite area smoothers designed to smooth within complicated geographical boundaries, where the boundary matters (e.g. you do not want to smooth across boundary features). See [soap](#) for details.

Broadly speaking the default penalized thin plate regression splines tend to give the best MSE performance, but they are slower to set up than the other bases. The knot based penalized cubic regression splines (with derivative based penalties) usually come next in MSE performance, with the P-splines doing just a little worse. However the P-splines are useful in non-standard situations.

All the preceding classes (and any user defined smooths with single penalties) may be used as marginal bases for tensor product smooths specified via `te`, `ti` or `t2` terms. Tensor product smooths are smooth functions of several variables where the basis is built up from tensor products of bases for smooths of fewer (usually one) variable(s) (marginal bases). The multiple penalties for these smooths are produced automatically from the penalties of the marginal smooths. Wood (2006b) and Wood, Scheipl and Faraway (2012), give the general recipe for these constructions.

**te** `te` smooths have one penalty per marginal basis, each of which is interpretable in a similar way to the marginal penalty from which it is derived. See Wood (2006b).

- t1** `ti` smooths exclude the basis functions associated with the ‘main effects’ of the marginal smooths, plus interactions other than the highest order specified. These provide a stable and interpretable way of specifying models with main effects and interactions. For example if we are interested in linear predictor  $f_1(x) + f_2(z) + f_3(x, z)$ , we might use model formula  $y \sim s(x) + s(z) + ti(x, z)$  or  $y \sim ti(x) + ti(z) + te(x, z)$ . A similar construction involving `te` terms instead will be much less statistically stable.
- t2** `t2` uses an alternative tensor product construction that results in more penalties each having a simple non-overlapping structure allowing use with the `gamm4` package. It is a natural generalization of the SS-ANOVA construction, but the penalties are a little harder to interpret. See Wood, Scheipl and Faraway (2012/13).

Tensor product smooths often perform better than isotropic smooths when the covariates of a smooth are not naturally on the same scale, so that their relative scaling is arbitrary. For example, if smoothing with respect to time and distance, an isotropic smoother will give very different results if the units are cm and minutes compared to if the units are metres and seconds: a tensor product smooth will give the same answer in both cases (see [te](#) for an example of this). Note that `te` terms are knot based, and the thin plate splines seem to offer no advantage over cubic or P-splines as marginal bases.

Some further specialist smoothers that are not suitable for use in tensor products are also available.

**Adaptive smoothers** `bs="ad"` Univariate and bivariate adaptive smooths are available (see [adaptive.smooth](#)). These are appropriate when the degree of smoothing should itself vary with the covariates to be smoothed, and the data contain sufficient information to be able to estimate the appropriate variation. Because this flexibility is achieved by splitting the penalty into several ‘basis penalties’ these terms are not suitable as components of tensor product smooths, and are not supported by `gamm`.

**Factor smooth interactions** `bs="fs"` Smooth factor interactions are often produced using `by` variables (see [gam.models](#)), but a special smoother class (see [factor.smooth.interaction](#)) is available for the case in which a smooth is required at each of a large number of factor levels (for example a smooth for each patient in a study), and each smooth should have the same smoothing parameter. The `"fs"` smoothers are set up to be efficient when used with `gamm`, and have penalties on each null sapce component (i.e. they are fully ‘random effects’).

smoothCon

---

*Prediction/Construction wrapper functions for GAM smooth terms*

---

**Description**

Wrapper functions for construction of and prediction from smooth terms in a GAM. The purpose of the wrappers is to allow user-transparent re-parameterization of smooth terms, in order to allow identifiability constraints to be absorbed into the parameterization of each term, if required. The routine also handles ‘by’ variables and construction of identifiability constraints automatically, although this behaviour can be over-ridden.

**Usage**

```
smoothCon(object, data, knots=NULL, absorb.cons=FALSE,
          scale.penalty=TRUE, n=nrow(data), dataX=NULL,
          null.space.penalty=FALSE, sparse.cons=0,
          diagonal.penalty=FALSE, apply.by=TRUE)
PredictMat(object, data, n=nrow(data))
```

**Arguments**

object	is a smooth specification object or a smooth object.
data	A data frame, model frame or list containing the values of the (named) covariates at which the smooth term is to be evaluated. If it’s a list then <code>n</code> must be supplied.
knots	An optional data frame supplying any knot locations to be supplied for basis construction.
absorb.cons	Set to TRUE in order to have identifiability constraints absorbed into the basis.
scale.penalty	should the penalty coefficient matrix be scaled to have approximately the same ‘size’ as the inner product of the terms model matrix with itself? This can improve the performance of <a href="#">gamm</a> fitting.
n	number of values for each covariate, or if a covariate is a matrix, the number of rows in that matrix: must be supplied explicitly if <code>data</code> is a list.
dataX	Sometimes the basis should be set up using data in <code>data</code> , but the model matrix should be constructed with another set of data provided in <code>dataX</code> — <code>n</code> is assumed to be the same for both. Facilitates smooth id’s.
null.space.penalty	Should an extra penalty be added to the smooth which will penalize the components of the smooth in the penalty null space: provides a way of penalizing terms out of the model altogether.

<code>apply.by</code>	set to FALSE to have basis setup exactly as in default case, but to return add an additional matrix <code>X0</code> to the return object, containing the model matrix without the <code>by</code> variable, if a <code>by</code> variable is present. Useful for <code>bam</code> discrete method setup.
<code>sparse.cons</code>	If 0 then default sum to zero constraints are used. If -1 then sweep and drop sum to zero constraints are used (default with <code>bam</code> ). If 1 then one coefficient is set to zero as constraint for sparse smooths. If 2 then sparse coefficient sum to zero constraints are used for sparse smooths. None of these options has an effect if the smooth supplies its own constraint.
<code>diagonal.penalty</code>	If TRUE then the smooth is reparameterized to turn the penalty into an identity matrix, with the final diagonal elements zeroed (corresponding to the penalty nullspace). May result in a matrix <code>diagRP</code> in the returned object for use by <code>PredictMat</code> .

## Details

These wrapper functions exist to allow smooths specified using `smooth.construct` and `Predict.matrix` method functions to be re-parameterized so that identifiability constraints are no longer required in fitting. This is done in a user transparent manner, but is typically of no importance in use of GAMs. The routine's also handle `by` variables and will create default identifiability constraints.

If a user defined smooth constructor handles `by` variables itself, then its returned smooth object should contain an object `by.done`. If this does not exist then `smoothCon` will use the default code. Similarly if a user defined `Predict.matrix` method handles `by` variables internally then the returned matrix should have a `"by.done"` attribute.

Default centering constraints, that terms should sum to zero over the covariates, are produced unless the smooth constructor includes a matrix `C` of constraints. To have no constraints (in which case you had better have a full rank penalty!) the matrix `C` should have no rows. There is an option to use centering constraint that generate no, or limited infill, if the smoother has a sparse model matrix.

`smoothCon` returns a list of smooths because factor `by` variables result in multiple copies of a smooth, each multiplied by the dummy variable associated with one factor level. `smoothCon` modifies the smooth object labels in the presence of `by` variables, to ensure that they are unique, it also stores the level of a `by` variable factor associated with a smooth, for later use by `PredictMat`.

The parameterization used by `gam` can be controlled via `gam.control`.

## Value

From `smoothCon` a list of smooth objects returned by the appropriate `smooth.construct` method function. If constraints are to be absorbed then the objects will have attributes `"qrc"` and `"nCons"`. `"nCons"` is the number of constraints. `"qrc"` is usually the qr decomposition of the constraint matrix (returned by `qr`), but if it is a single positive integer it is the index of the coefficient to set to zero, and if it is a negative number then this indicates that the parameters are to sum to zero.

For `predictMat` a matrix which will map the parameters associated with the smooth to the vector of values of the smooth evaluated at the covariate values given in `object`.

sp.vcov

*Extract smoothing parameter estimator covariance matrix from (RE)ML GAM fit*

---

## Description

Extracts the estimated covariance matrix for the log smoothing parameter estimates from a (RE)ML estimated gam object, provided the fit was with a method that evaluated the required Hessian.

## Usage

```
sp.vcov(x)
```

## Arguments

x a fitted model object of class gam as produced by gam().

## Details

Just extracts the inverse of the hessian matrix of the negative (restricted) log likelihood w.r.t the log smoothing parameters, if this has been obtained as part of fitting.

**Value**

A matrix corresponding to the estimated covariance matrix of the log smoothing parameter estimators, if this can be extracted, otherwise `NULL`. If the scale parameter has been (RE)ML estimated (i.e. if the method was "ML" or "REML" and the scale parameter was unknown) then the last row and column relate to the log scale parameter.

```
require(mgcv)
n <- 100
x <- runif(n); z <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10)+s(z),knots=list(x=seq(0,1,length=10)),
           method="REML")
sp.vcov(mod)
```

---

spasm.construct

*Experimental sparse smoothers*

---

**Description**

These are experimental sparse smoothing functions, and should be left well alone!

**Usage**

```
spasm.construct(object,data)
spasm.sp(object,sp,w=rep(1,object$noobs),get.trH=TRUE,block=0,centre=FALSE)
spasm.smooth(object,X,residual=FALSE,block=0)
```

**Arguments**

<code>object</code>	sparse smooth object
<code>data</code>	data frame
<code>sp</code>	smoothing parameter value
<code>w</code>	optional weights
<code>get.trH</code>	Should (estimated) trace of sparse smoother matrix be returned
<code>block</code>	index of block, 0 for all blocks

centre	should sparse smooth be centred?
x	what to smooth
residual	apply residual operation?

**WARNING**

It is not recommended to use these yet

---

step.gam

---

*Alternatives to step.gam*

---

**Description**

There is no `step.gam` in package `mgcv`. The `mgcv` default for model selection is to use either prediction error criteria such as GCV, GACV, Mallows' Cp/AIC/UBRE or the likelihood based methods of REML or ML. Since the smoothness estimation part of model selection is done in this way it is logically most consistent to perform the rest of model selection in the same way. i.e. to decide which terms to include or omit by looking at changes in GCV, AIC, REML etc.

To facilitate fully automatic model selection the package implements two smooth modification techniques which can be used to allow smooths to be shrunk to zero as part of smoothness selection.

**Shrinkage smoothers** are smoothers in which a small multiple of the identity matrix is added to the smoothing penalty, so that strong enough penalization will shrink all the coefficients of the smooth to zero. Such smoothers can effectively be penalized out of the model altogether, as part of smoothing parameter estimation. 2 classes of these shrinkage smoothers are implemented: "cs" and "ts", based on cubic regression spline and thin plate regression spline smoothers (see [s](#))

**Null space penalization** An alternative is to construct an extra penalty for each smooth which penalizes the space of functions of zero wiggleness according to its existing penalties. If all the smoothing parameters for such a term tend to infinity then the term is penalized to zero, and is effectively dropped from the model. The advantage of this approach is that it can be implemented automatically for any smooth. The `select` argument to `gam` causes this latter approach to be used. Unpenalized terms (e.g. `s(x, fx=TRUE)`) remain unpenalized.

REML and ML smoothness selection are equivalent under this approach, and simulation evidence suggests that they tend to perform a little better than prediction error criteria, for model selection.

summary.gam

*Summary for a GAM fit***Description**

Takes a fitted `gam` object produced by `gam()` and produces various useful summaries from it. (See [sink](#) to divert output to a file.)

**Usage**

```
## S3 method for class 'gam'
summary(object, dispersion=NULL, freq=FALSE, p.type = 0, ...)

## S3 method for class 'summary.gam'
print(x, digits = max(3, getOption("digits") - 3),
      signif.stars = getOption("show.signif.stars"), ...)
```

## Arguments

<code>object</code>	a fitted <code>gam</code> object as produced by <code>gam()</code> .
<code>x</code>	a <code>summary.gam</code> object produced by <code>summary.gam()</code> .
<code>dispersion</code>	A known dispersion parameter. <code>NULL</code> to use estimate or default (e.g. 1 for Poisson).
<code>freq</code>	By default p-values for parametric terms are calculated using the Bayesian estimated covariance matrix of the parameter estimators. If this is set to <code>TRUE</code> then the frequentist covariance matrix of the parameters is used instead.
<code>p.type</code>	determines how p-values are computed for smooth terms. 0 uses a test statistic with distribution determined by the un-rounded edf of the term. 1 uses upwardly biased rounding of the edf and -1 uses a version of the test statistic with a null distribution that has to be simulated. 5 is the approximation in Wood (2006). Other options are poor, generate a warning, and are only of research interest. See details.
<code>digits</code>	controls number of digits printed in output.
<code>signif.stars</code>	Should significance stars be printed alongside output.
<code>...</code>	other arguments.

## Details

Model degrees of freedom are taken as the trace of the influence (or hat) matrix  $\mathbf{A}$  for the model fit. Residual degrees of freedom are taken as number of data minus model degrees of freedom. Let  $\mathbf{P}_i$  be the matrix giving the parameters of the  $i$ th smooth when applied to the data (or pseudodata in the generalized case) and let  $\mathbf{X}$  be the design matrix of the model. Then  $tr(\mathbf{X}\mathbf{P}_i)$  is the edf for the  $i$ th term. Clearly this definition causes the edf's to add up properly! An alternative version of EDF is more appropriate for p-value computation, and is based on the trace of  $2\mathbf{A} - \mathbf{A}\mathbf{A}$ .

`print.summary.gam` tries to print various bits of summary information useful for term selection in a pretty way.

P-values for smooth terms are usually based on a test statistic motivated by an extension of Nychka's (1988) analysis of the frequentist properties of Bayesian confidence intervals for smooths (Marra and Wood, 2012). These have better frequentist performance (in terms of power and distribution under the null) than the alternative strictly frequentist approximation. When the Bayesian intervals have good across the function properties then the p-values have close to the correct null distribution and reasonable power (but there are no optimality results for the power). Full details are in Wood (2013b), although what is computed is actually a slight variant in which the components of the test statistic are weighted by the iterative fitting weights.

Note that for terms with no unpenalized terms (such as Gaussian random effects) the Nychka (1988) requirement for smoothing bias to be substantially less than variance breaks down (see e.g. appendix of Marra and Wood, 2012), and this results in incorrect null distribution for p-values computed using the above approach. In this case it is necessary to use an alternative approach designed for random effects variance components, and this is done. See Wood (2013a) for details: the test is based on a likelihood ratio statistic (with the reference distribution appropriate for the null hypothesis on the boundary of the parameter space).

All p-values are computed without considering uncertainty in the smoothing parameter estimates.

In simulations the p-values have best behaviour under ML smoothness selection, with REML coming second. In general the p-values behave well, but neglecting smoothing parameter uncertainty means that they may be somewhat too low when smoothing parameters are highly uncertain. High uncertainty happens in particular when smoothing parameters are poorly identified, which can occur with nested smooths or highly correlated covariates (high concurvity).

If `p.type=5` then the frequentist approximation for p-values of smooth terms described in section 4.8.5 of Wood (2006) is used. The approximation is not as good as the default, and is no longer recommended.

By default the p-values for parametric model terms are also based on Wald tests using the Bayesian covariance matrix for the coefficients. This is appropriate when there are "re" terms present, and is otherwise rather similar to the results using the frequentist covariance matrix (`freq=TRUE`), since the parametric terms themselves are usually unpenalized. Default P-values for parameteric terms that are penalized using the `paraPen` argument will not be good. However if such terms represent conventional random effects with full rank penalties, then setting `freq=TRUE` is appropriate.

## Value

`summary.gam` produces a list of summary information for a fitted `gam` object.

<code>p.coeff</code>	is an array of estimates of the strictly parametric model coefficients.
<code>p.t</code>	is an array of the <code>p.coeff</code> 's divided by their standard errors.
<code>p.pv</code>	is an array of p-values for the null hypothesis that the corresponding parameter is zero. Calculated with reference to the t distribution with the estimated residual degrees of freedom for the model fit if the dispersion parameter has been estimated, and the standard normal if not.
<code>m</code>	The number of smooth terms in the model.
<code>chi.sq</code>	An array of test statistics for assessing the significance of model smooth terms. See details.
<code>s.pv</code>	An array of approximate p-values for the null hypotheses that each smooth term is zero. Be warned, these are only approximate.
<code>se</code>	array of standard error estimates for all parameter estimates.
<code>r.sq</code>	The adjusted r-squared for the model. Defined as the proportion of variance explained, where original variance and residual variance are both estimated using unbiased estimators. This quantity can be negative if your model is worse than a one parameter constant model, and can be higher for the smaller of two nested models! The proportion null deviance explained is probably more appropriate for non-normal errors. Note that <code>r.sq</code> does not include any offset in the one parameter model.
<code>dev.expl</code>	The proportion of the null deviance explained by the model. The null deviance is computed taking account of any offset, so <code>dev.expl</code> can be substantially lower than <code>r.sq</code> when an offset is present.
<code>edf</code>	array of estimated degrees of freedom for the model terms.
<code>residual.df</code>	estimated residual degrees of freedom.
<code>n</code>	number of data.
<code>np</code>	number of model coefficients (regression coefficients, not smoothing parameters or other parameters of likelihood).
<code>rank</code>	apparent model rank.
<code>method</code>	The smoothing selection criterion used.
<code>sp.criterion</code>	The minimized value of the smoothness selection criterion. Note that for ML and REML methods, what is reported is the negative log marginal likelihood or negative log restricted likelihood.
<code>scale</code>	estimated (or given) scale parameter.

<code>family</code>	the family used.
<code>formula</code>	the original GAM formula.
<code>dispersion</code>	the scale parameter.
<code>pTerms.df</code>	the degrees of freedom associated with each parametric term (excluding the constant).
<code>pTerms.chi.sq</code>	a Wald statistic for testing the null hypothesis that the each parametric term is zero.
<code>pTerms.pv</code>	p-values associated with the tests that each term is zero. For penalized fits these are approximate. The reference distribution is an appropriate chi-squared when the scale parameter is known, and is based on an F when it is not.
<code>cov.unscaled</code>	The estimated covariance matrix of the parameters (or estimators if <code>freq=TRUE</code> ), divided by scale parameter.
<code>cov.scaled</code>	The estimated covariance matrix of the parameters (estimators if <code>freq=TRUE</code> ).
<code>p.table</code>	significance table for parameters
<code>s.table</code>	significance table for smooths
<code>p.Terms</code>	significance table for parametric model terms

## WARNING

The p-values are approximate and neglect smoothing parameter uncertainty. They are likely to be somewhat too low when smoothing parameter estimates are highly uncertain: do read the details section. If the exact values matter, read Wood (2013a or b).

P-values for terms penalized via ‘paraPen’ are unlikely to be correct.

## Description

Alternative to [te](#) for defining tensor product smooths in a [gam](#) formula. Results in a construction in which the penalties are non-overlapping multiples of identity matrices (with some rows and columns zeroed). The construction, which is due to Fabian Scheipl ([mgcv](#) implementation, 2010), is analogous to Smoothing Spline ANOVA (Gu, 2002), but using low rank penalized regression spline marginals. The main advantage of this construction is that it is useable with [gamm4](#) from package [gamm4](#).

## Usage

```
t2(..., k=NA, bs="cr", m=NA, d=NA, by=NA, xt=NULL,
    id=NULL, sp=NULL, full=FALSE, ord=NULL)
```

## Arguments

<code>...</code>	a list of variables that are the covariates that this smooth is a function of.
<code>k</code>	the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See <a href="#">choose.k</a> for further information.
<code>bs</code>	array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See <a href="#">smooth.terms</a> for details and full list. User defined bases can also be used here (see <a href="#">smooth.construct</a> for an example). If only one basis code is given then this is used for all bases.
<code>m</code>	The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different <code>m</code> for each margin. For marginals that take vector <code>m</code> (e.g. <a href="#">p.spline</a> and <a href="#">Duchon.spline</a> ), then a list can be supplied, with a vector element for each margin. NA autoinitializes. <code>m</code> is ignored by some bases (e.g. "cr").
<code>d</code>	array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set <code>d=c(2, 1)</code> . Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.
<code>by</code>	a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a 'varying coefficient model' results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details).
<code>xt</code>	Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.
<code>id</code>	A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same <code>id</code> then they will have the same smoothing parameters, and, by default, the same

	bases (first occurrence defines basis type, but data from all terms used in basis construction).
<code>sp</code>	any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in <code>sp</code> argument to <code>gam</code> . Ignored by <code>gamm</code> .
<code>full</code>	If <code>TRUE</code> then there is a separate penalty for each combination of null space column and range space. This gives strict invariance. If <code>FALSE</code> each combination of null space and range space generates one penalty, but the columns of each null space basis are treated as one group. The latter is more parsimonious, but does mean that invariance is only achieved by an arbitrary rescaling of null space basis vectors.
<code>ord</code>	an array giving the orders of terms to retain. Here order means number of marginal range spaces used in the construction of the component. <code>NULL</code> to retain everything.

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices. These are reparameterized so that the penalty is zero everywhere, except for some elements on the leading diagonal, which all have the same non-zero value. This reparameterization results in an unpenalized and a penalized subset of parameters, for each marginal basis (see e.g. appendix of Wood, 2004, for details).

The re-parameterized marginal bases are then combined to produce a basis for a single function of all the covariates (dimension given by the product of the dimensions of the marginal bases). In this set up there are multiple penalty matrices — all zero, but for a mixture of a constant and zeros on the leading diagonal. No two penalties have a non-zero entry in the same place.

Essentially the basis for the tensor product can be thought of as being constructed from a set of products of the penalized (range) or unpenalized (null) space bases of the marginal smooths (see Gu, 2002, section 2.4). To construct one of the set, choose either the null space or the range space from each marginal, and from these bases construct a product basis. The result is subject to a ridge penalty (unless it happens to be a product entirely of marginal null spaces). The whole basis for the smooth is constructed from all the different product bases that can be constructed in this way. The separately penalized components of the smooth basis each have an interpretation in terms of the ANOVA - decomposition of the term. See [pen.edf](#) for some further information.

Note that there are two ways to construct the product. When `full=FALSE` then the null space bases are treated as a whole in each product, but when `full=TRUE` each null space column is treated as a separate null space. The latter results in more penalties, but is the strict analog of the SS-ANOVA approach.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

Note also that GAMs constructed from lower rank tensor product smooths are nested within GAMs constructed from higher rank tensor product smooths if the same marginal bases are used in both cases (the marginal smooths themselves are just special cases of tensor product smooths.)

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

### Value

A class `t2.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

<code>margin</code>	A list of <code>smooth.spec</code> objects of the type returned by <code>s</code> , defining the basis from which the tensor product smooth is constructed.
<code>term</code>	An array of text strings giving the names of the covariates that the term is a function of.
<code>by</code>	is the name of any <code>by</code> variable as text ("NA" for none).
<code>fx</code>	logical array with element for each penalty of the term (tensor product smooths have multiple penalties). TRUE if the penalty is to be ignored, FALSE, otherwise.
<code>label</code>	A suitable text label for this smooth term.
<code>dim</code>	The dimension of the smoother - i.e. the number of covariates that it is a function of.
<code>mp</code>	TRUE is multiple penalties are to be used (default).
<code>np</code>	TRUE to re-parameterize 1-D marginal smooths in terms of function values (default).
<code>id</code>	the <code>id</code> argument supplied to <code>te</code> .
<code>sp</code>	the <code>sp</code> argument supplied to <code>te</code> .

---

## Description

Functions used for the definition of tensor product smooths and interactions within `gam` model formulae. `te` produces a full tensor product smooth, while `ti` produces a tensor product interaction, appropriate when the main effects (and any lower interactions) are also present.

The functions do not evaluate the smooth - they exist purely to help set up a model using tensor product based smooths. Designed to construct tensor products from any marginal smooths with a basis-penalty representation (with the restriction that each marginal smooth must have only one penalty).

## Usage

```
te(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
      mp=TRUE, np=TRUE, xt=NULL, id=NULL, sp=NULL)
ti(..., k=NA, bs="cr", m=NA, d=NA, by=NA, fx=FALSE,
      np=TRUE, xt=NULL, id=NULL, sp=NULL, mc=NULL)
```

## Arguments

- |     |  |
|-----|--|
| ... | a list of variables that are the covariates that this smooth is a function of.   |
| k   | the dimension(s) of the bases used to represent the smooth term. If not supplied then set to $5^d$ . If supplied as a single number then this basis dimension is used for each basis. If supplied as an array then the elements are the dimensions of the component (marginal) bases of the tensor product. See <a href="#">choose.k</a> for further information.  |
| bs  | array (or single character string) specifying the type for each marginal basis. "cr" for cubic regression spline; "cs" for cubic regression spline with shrinkage; "cc" for periodic/cyclic cubic regression spline; "tp" for thin plate regression spline; "ts" for t.p.r.s. with extra shrinkage. See <a href="#">smooth.terms</a> for details and full list. User defined bases can also be used here (see <a href="#">smooth.construct</a> for an example). If only one basis code is given then this is used for all bases. |
| m   | The order of the spline and its penalty (for smooth classes that use this) for each term. If a single number is given then it is used for all terms. A vector can be used to supply a different <code>m</code> for each margin. For marginals that take vector <code>m</code> (e.g. <a href="#">p.spline</a> and <a href="#">Duchon.spline</a> ), then a list can be supplied, with a vector element for each margin. NA autoinitializes. <code>m</code> is ignored by some bases (e.g. "cr").                                   |
| d   | array of marginal basis dimensions. For example if you want a smooth for 3 covariates made up of a tensor product of a 2 dimensional t.p.r.s. basis and a 1-dimensional basis, then set <code>d=c(2, 1)</code> . Incompatibilities between built in basis types and dimension will be resolved by resetting the basis type.  |

by	a numeric or factor variable of the same dimension as each covariate. In the numeric vector case the elements multiply the smooth evaluated at the corresponding covariate values (a ‘varying coefficient model’ results). In the factor case causes a replicate of the smooth to be produced for each factor level. See <a href="#">gam.models</a> for further details. May also be a matrix if covariates are matrices: in this case implements linear functional of a smooth (see <a href="#">gam.models</a> and <a href="#">linear.functional.terms</a> for details).
fx	indicates whether the term is a fixed d.f. regression spline (TRUE) or a penalized regression spline (FALSE).
mp	TRUE to use multiple penalties for the smooth. FALSE to use only a single penalty: single penalties are not recommended and are deprecated - they tend to allow only rather wiggly models.
np	TRUE to use the ‘normal parameterization’ for a tensor product smooth. This represents any 1-d marginal smooths via parameters that are function values at ‘knots’, spread evenly through the data. The parameterization makes the penalties easily interpretable, however it can reduce numerical stability in some cases.
xt	Either a single object, providing any extra information to be passed to each marginal basis constructor, or a list of such objects, one for each marginal basis.
id	A label or integer identifying this term in order to link its smoothing parameters to others of the same type. If two or more smooth terms have the same id then they will have the same smoothing parameters, and, by default, the same bases (first occurrence defines basis type, but data from all terms used in basis construction).
sp	any supplied smoothing parameters for this term. Must be an array of the same length as the number of penalties for this smooth. Positive or zero elements are taken as fixed smoothing parameters. Negative elements signal auto-initialization. Over-rides values supplied in sp argument to <a href="#">gam</a> . Ignored by <a href="#">gamm</a> .
mc	For ti smooths you can specify which marginals should have centering constraints applied, by supplying 0/1 or FALSE/TRUE values for each marginal in this vector. By default all marginals are constrained, which is what is appropriate for, e.g., functional ANOVA models. Note that 'ti' only applies constraints to the marginals, so if you turn off all marginal constraints the term will have no identifiability constraints. Only use this if you really understand how marginal constraints work.

## Details

Smooths of several covariates can be constructed from tensor products of the bases used to represent smooths of one (or sometimes more) of the covariates. To do this ‘marginal’ bases are produced with associated model matrices and penalty matrices, and these are then combined in the manner described in [tensor.prod.model.matrix](#) and [tensor.prod.penalties](#), to produce a single model matrix for the smooth, but multiple penalties (one for each marginal basis). The basis dimension of the whole smooth is the product of the basis dimensions of the marginal smooths.

An option for operating with a single penalty (The Kronecker product of the marginal penalties) is provided, but it is rarely of practical use, and is deprecated: the penalty is typically so rank deficient that even the smoothest resulting model will have rather high estimated degrees of freedom.

Tensor product smooths are especially useful for representing functions of covariates measured in different units, although they are typically not quite as nicely behaved as t.p.r.s. smooths for well scaled covariates.

It is sometimes useful to investigate smooth models with a main-effects + interactions structure, for example

$$f_1(x) + f_2(z) + f_3(x, z)$$

This functional ANOVA decomposition is supported by `ti` terms, which produce tensor product interactions from which the main effects have been excluded, under the assumption that they will be included separately. For example the `~ ti(x) + ti(z) + ti(x, z)` would produce the above main effects + interaction structure. This is much better than attempting the same thing with `sor te` terms representing the interactions (although `mgcv` does not forbid it). Technically `ti` terms are very simple: they simply construct tensor product bases from marginal smooths to which identifiability constraints (usually sum-to-zero) have already been applied: correct nesting is then automatic (as with all interactions in a GLM framework).

The ‘normal parameterization’ (`np=TRUE`) re-parameterizes the marginal smooths of a tensor product smooth so that the parameters are function values at a set of points spread evenly through the range of values of the covariate of the smooth. This means that the penalty of the tensor product associated with any particular covariate direction can be interpreted as the penalty of the appropriate marginal smooth applied in that direction and averaged over the smooth. Currently this is only done for marginals of a single variable. This parameterization can reduce numerical stability when used with marginal smooths other than `"cc"`, `"cr"` and `"cs"`: if this causes problems, set `np=FALSE`.

Note that tensor product smooths should not be centred (have identifiability constraints imposed) if any marginals would not need centering. The constructor for tensor product smooths ensures that this happens.

The function does not evaluate the variable arguments.

## Value

A class `tensor.smooth.spec` object defining a tensor product smooth to be turned into a basis and penalties by the `smooth.construct.tensor.smooth.spec` function.

The returned object contains the following items:

<code>margin</code>	A list of <code>smooth.spec</code> objects of the type returned by <code>s</code> , defining the basis from which the tensor product smooth is constructed.
<code>term</code>	An array of text strings giving the names of the covariates that the term is a function of.
<code>by</code>	is the name of any <code>by</code> variable as text ( <code>"NA"</code> for none).
<code>fx</code>	logical array with element for each penalty of the term (tensor product smooths have multiple penalties). <code>TRUE</code> if the penalty is to be ignored, <code>FALSE</code> , otherwise.
<code>label</code>	A suitable text label for this smooth term.
<code>dim</code>	The dimension of the smoother - i.e. the number of covariates that it is a function of.
<code>mp</code>	<code>TRUE</code> if multiple penalties are to be used (default).
<code>np</code>	<code>TRUE</code> to re-parameterize 1-D marginal smooths in terms of function values (default).
<code>id</code>	the <code>id</code> argument supplied to <code>te</code> .
<code>sp</code>	the <code>sp</code> argument supplied to <code>te</code> .
<code>inter</code>	<code>TRUE</code> if the term was generated by <code>ti</code> , <code>FALSE</code> otherwise.
<code>mc</code>	the argument <code>mc</code> supplied to <code>ti</code> .

---

tensor.prod.model.matrix

*Utility functions for constructing tensor product smooths*

---

## Description

Produce model matrices or penalty matrices for a tensor product smooth from the model matrices or penalty matrices for the marginal bases of the smooth.

## Usage

```

tensor.prod.model.matrix(X)
tensor.prod.penalties(S)

```

## Arguments

X	a list of model matrices for the marginal bases of a smooth
S	a list of penalties for the marginal bases of a smooth.

## Details

If  $X[[1]]$ ,  $X[[2]]$  ...  $X[[m]]$  are the model matrices of the marginal bases of a tensor product smooth then the  $i$ th row of the model matrix for the whole tensor product smooth is given by  $X[[1]][i,] \%x\% X[[2]][i,] \%x\% \dots X[[m]][i,]$ , where  $\%x\%$  is the Kronecker product. Of course the routine operates column-wise, not row-wise!

If  $S[[1]]$ ,  $S[[2]]$  ...  $S[[m]]$  are the penalty matrices for the marginal bases, and  $I[[1]]$ ,  $I[[2]]$  ...  $I[[m]]$  are corresponding identity matrices, each of the same dimension as its corresponding penalty, then the tensor product smooth has  $m$  associate penalties of the form:

```

S[[1]] \%x\% I[[2]] \%x\% ... I[[m]],
I[[1]] \%x\% S[[2]] \%x\% ... I[[m]]
...
I[[1]] \%x\% I[[2]] \%x\% ... S[[m]].

```

Of course it's important that the model matrices and penalty matrices are presented in the same order when constructing tensor product smooths.

## Value

Either a single model matrix for a tensor product smooth, or a list of penalty terms for a tensor product smooth.

---

Tweedie	<i>GAM Tweedie families</i>
---------	-----------------------------

---

Description

Tweedie families, designed for use with [gam](#) from the `mgcv` library. Restricted to variance function powers between 1 and 2. A useful alternative to [quasi](#) when a full likelihood is desirable. Tweedie is for use with fixed `p`. `tw` is for use when `p` is to be estimated during fitting. For fixed `p` between 1 and 2 the Tweedie is an exponential family distribution with variance given by the mean to the power `p`.  
`tw` is only useable with [gam](#), not `bam` or `gamm`. Tweedie works with all three.

Usage

```
Tweedie(p=1, link = power(0))
tw(theta = NULL, link = "log", a=1.01, b=1.99)
```

Arguments

<code>p</code>	the variance of an observation is proportional to its mean to the power <code>p</code> . <code>p</code> must be greater than 1 and less than or equal to 2. 1 would be Poisson, 2 is gamma.
<code>link</code>	The link function: one of "log", "identity", "inverse", "sqrt", or a <a href="#">power</a> link (Tweedie only).
<code>theta</code>	Related to the Tweedie power parameter by $p = \exp(a + b \exp(\theta)) / (1 + \exp(\theta))$ . If this is supplied as a positive value then it is taken as the fixed value for <code>p</code> . If it is a negative values then its absolute value is taken as the initial value for <code>p</code> .
<code>a</code>	lower limit on <code>p</code> for optimization.
<code>b</code>	upper limit on <code>p</code> for optimization.

## Details

A Tweedie random variable with  $1 < p < 2$  is a sum of  $N$  gamma random variables where  $N$  has a Poisson distribution. The  $p=1$  case is a generalization of a Poisson distribution and is a discrete distribution supported on integer multiples of the scale parameter. For  $1 < p < 2$  the distribution is supported on the positive reals with a point mass at zero.  $p=2$  is a gamma distribution. As  $p$  gets very close to 1 the continuous distribution begins to converge on the discretely supported limit at  $p=1$ , and is therefore highly multimodal. See [ldTweedie](#) for more on this behaviour.

Tweedie is based partly on the [poisson](#) family, and partly on `tweedie` from the `statmod` package. It includes extra components to work with all `mgcv` GAM fitting methods as well as an `aic` function.

The Tweedie density involves a normalizing constant with no closed form, so this is evaluated using the series evaluation method of Dunn and Smyth (2005), with extensions to also compute the derivatives w.r.t.  $p$  and the scale parameter. Without restricting  $p$  to (1,2) the calculation of Tweedie densities is more difficult, and there does not currently seem to be an implementation which offers any benefit over [quasi](#). If you need this case then the `tweedie` package is the place to start.

## Value

For `Tweedie`, an object inheriting from class `family`, with additional elements

<code>dvar</code>	the function giving the first derivative of the variance function w.r.t. $\mu$ .
<code>d2var</code>	the function giving the second derivative of the variance function w.r.t. $\mu$ .
<code>ls</code>	A function returning a 3 element array: the saturated log likelihood followed by its first 2 derivatives w.r.t. the scale parameter.

For `tw`, an object of class `extended.family`.

---

uniquecombs

*find the unique rows in a matrix*

---

## Description

This routine returns a matrix or data frame containing all the unique rows of the matrix or data frame supplied as its argument. That is, all the duplicate rows are stripped out. Note that the ordering of the rows on exit is not the same as on entry. It also returns an index attribute for relating the result back to the original matrix.

## Usage

```
uniquecombs(x)
```

## Arguments

`x` is an R matrix (numeric), or data frame.

## Details

Models with more parameters than unique combinations of covariates are not identifiable. This routine provides a means of evaluating the number of unique combinations of covariates in a model. The routine calls compiled C code, and is based on sorting, with consequent  $O(n \log(n))$  cost. In principle a hash table based solution should be only  $O(n)$ .

[unique](#) and [duplicated](#), can sometimes be used in place of this, if the full index is not needed. Relative performance is variable.

If `x` is not a matrix or data frame on entry then an attempt is made to coerce it to a data frame.

## Value

A matrix or data frame consisting of the unique rows of `x` (in arbitrary order).

The matrix or data frame has an "index" attribute. `index[i]` gives the row of the returned matrix that contains row `i` of the original matrix.

print(X)
Xu <- uniquecombs(X);Xu
ind <- attr(Xu,"index")
## find the value for row 3 of the original from Xu
Xu[ind[3],];X[3,]

## data frame example...
df <- data.frame(f=factor(c("er",3,"b","er",3,3,1,2,"b")),
  x=c(.5,1,1.4,.5,1,.6,4,3,1.7))
uniquecombs(df)
```

---

vcov.gam

---

*Extract parameter (estimator) covariance matrix from GAM fit*

---

**Description**

Extracts the Bayesian posterior covariance matrix of the parameters or frequentist covariance matrix of the parameter estimators from a fitted `gam` object.

**Usage**

```
## S3 method for class 'gam'
vcov(object, freq = FALSE, dispersion = NULL, unconditional=FALSE, ...)
```

**Arguments**

<code>object</code>	fitted model object of class <code>gam</code> as produced by <code>gam()</code> .
<code>freq</code>	TRUE to return the frequentist covariance matrix of the parameter estimators, FALSE to return the Bayesian posterior covariance matrix of the parameters.
<code>dispersion</code>	a value for the dispersion parameter: not normally used.
<code>unconditional</code>	if TRUE (and <code>freq==FALSE</code> ) then the Bayesian smoothing parameter uncertainty corrected covariance matrix is returned, if available.
<code>...</code>	other arguments, currently ignored.

**Details**

Basically, just extracts `object$Ve` or `object$Vp` from a [gamObject](#).

**Value**

A matrix corresponding to the estimated frequentist covariance matrix of the model parameter estimators/coefficients, or the estimated posterior covariance matrix of the parameters, depending on the argument `freq`.

**Examples**

```
require(mgcv)
n <- 100
x <- runif(n)
y <- sin(x*2*pi) + rnorm(n)*.2
mod <- gam(y~s(x,bs="cc",k=10),knots=list(x=seq(0,1,length=10)))
diag(vcov(mod))
```

---

vis.gam

---

*Visualization of GAM objects*

---

**Description**

Produces perspective or contour plot views of `gam` model predictions, fixing all but the values in `view` to the values supplied in `cond`.

**Usage**

```
vis.gam(x, view=NULL, cond=list(), n.grid=30, too.far=0, col=NA,
        color="heat", contour.col=NULL, se=-1, type="link",
        plot.type="persp", zlim=NULL, nCol=50, ...)
```

**Arguments**

<code>x</code>	a <code>gam</code> object, produced by <code>gam()</code>
<code>view</code>	an array containing the names of the two main effect terms to be displayed on the x and y dimensions of the plot. If omitted the first two suitable terms will be used. Note that variables coerced to factors in the model formula won't work as view variables, and <code>vis.gam</code> can not detect that this has happened when setting defaults.

<code>cond</code>	a named list of the values to use for the other predictor terms (not in <code>view</code> ). Variables omitted from this list will have the closest observed value to the median for continuous variables, or the most commonly occurring level for factors. Parametric matrix variables have all the entries in each column set to the observed column entry closest to the column median.
<code>n.grid</code>	The number of grid nodes in each direction used for calculating the plotted surface.
<code>too.far</code>	plot grid nodes that are too far from the points defined by the variables given in <code>view</code> can be excluded from the plot. <code>too.far</code> determines what is too far. The grid is scaled into the unit square along with the <code>view</code> variables and then grid nodes more than <code>too.far</code> from the predictor variables are excluded.
<code>col</code>	The colours for the facets of the plot. If this is NA then if <code>se&gt;0</code> the facets are transparent, otherwise the colour scheme specified in <code>color</code> is used. If <code>col</code> is not NA then it is used as the facet colour.
<code>color</code>	the colour scheme to use for plots when <code>se&lt;=0</code> . One of "topo", "heat", "cm", "terrain", "gray" or "bw". Schemes "gray" and "bw" also modify the colors used when <code>se&gt;0</code> .
<code>contour.col</code>	sets the colour of contours when using <code>plot.type="contour"</code> . Default scheme used if NULL.
<code>se</code>	if less than or equal to zero then only the predicted surface is plotted, but if greater than zero, then 3 surfaces are plotted, one at the predicted values minus <code>se</code> standard errors, one at the predicted values and one at the predicted values plus <code>se</code> standard errors.
<code>type</code>	"link" to plot on linear predictor scale and "response" to plot on the response scale.
<code>plot.type</code>	one of "contour" or "persp".
<code>zlim</code>	a two item array giving the lower and upper limits for the z-axis scale. NULL to choose automatically.
<code>nCol</code>	The number of colors to use in color schemes.
<code>...</code>	other options to pass on to <code>persp</code> , <code>image</code> or <code>contour</code> . In particular <code>ticktype="detailed"</code> will add proper axes labelling to the plots.

## Details

The x and y limits are determined by the ranges of the terms named in `view`. If `se<=0` then a single (height colour coded, by default) surface is produced, otherwise three (by default see-through) meshes are produced at mean and +/- `se` standard errors. Parts of the x-y plane too far from data can be excluded by setting `too.far`

All options to the underlying graphics functions can be reset by passing them as extra arguments  
 . . . : such supplied values will always over-ride the default values used by `vis.gam`.

## Value

Simply produces a plot.

## WARNINGS

The routine can not detect that a variable has been coerced to factor within a model formula, and will therefore fail if such a variable is used as a `view` variable. When setting default `view` variables it can not detect this situation either, which can cause failures if the coerced variables are the first, otherwise suitable, variables encountered.

ziP

*GAM zero-inflated Poisson regression family***Description**

Family for use with `gam`, implementing regression for zero inflated Poisson data when the complementary log log of the zero probability is linearly dependent on the log of the Poisson parameter. Use with great care, noting that simply having many zero response observations is not an indication of zero inflation: the question is whether you have too many zeroes given the specified model.

This sort of model is really only appropriate when none of your covariates help to explain the zeroes in your data. If your covariates predict which observations are likely to have zero mean then adding a zero inflated model on top of this is likely to lead to identifiability problems. Identifiability problems may lead to fit failures, or absurd values for the linear predictor or predicted values.

**Usage**

```
ziP(theta = NULL, link = "identity", b=0)
```

**Arguments**

<code>theta</code>	the 2 parameters controlling the slope and intercept of the linear transform of the mean controlling the zero inflation rate. If supplied then treated as fixed parameters ( $\theta_1$ and $\theta_2$ ), otherwise estimated.
<code>link</code>	The link function: only the "identity" is currently supported.
<code>b</code>	a non-negative constant, specifying the minimum dependence of the zero inflation rate on the linear predictor.

**Details**

The probability of a zero count is given by  $1 - p$ , whereas the probability of count  $y > 0$  is given by the truncated Poisson probability function  $p\mu^y/((\exp(\mu) - 1)y!)$ . The linear predictor gives  $\log \mu$ , while  $\eta = \log(-\log(1 - p))$  and  $\eta = \theta_1 + \{b + \exp(\theta_2)\} \log \mu$ . The `theta` parameters are estimated alongside the smoothing parameters. Increasing the `b` parameter from zero can greatly reduce identifiability problems, particularly when there are very few non-zero data.

The fitted values for this model are the log of the Poisson parameter. Use the `predict` function with `type=="response"` to get the predicted expected response. Note that the `theta` parameters reported in model summaries are  $\theta_1$  and  $b + \exp(\theta_2)$ .

These models should be subject to very careful checking, especially if fitting has not converged. It is quite easy to set up models with identifiability problems, particularly if the data are not really zero inflated, but simply have many zeroes because the mean is very low in some parts of the covariate space. See example for some obvious checks. Take convergence warnings seriously.

**Value**

An object of class `extended.family`.

**WARNINGS**

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes \*given the model mean\* may imply zero inflation.

b2 <- gam(y~s(x0)+s(x1)+s(x2)+s(x3),family=ziP(b=.3),data=dat)

```

ziplss

*Zero inflated Poisson location-scale model family*

## Description

The `ziplss` family implements a zero inflated Poisson model in which one linear predictor controls the probability of presence and the other controls the mean given presence. Useable only with `gam`, the linear predictors are specified via a list of formulae. Should be used with care: simply having a large number of zeroes is not an indication of zero inflation.

Requires integer count data.

## Usage

```
ziplss(link=list("identity","identity"))
```

## Arguments

<code>link</code>	two item list specifying the link - currently only identity links are possible, as parameterization is directly in terms of log of Poisson response and logit of probability of presence.
-------------------	---

## Details

Used with `gam` to fit 2 stage zero inflated Poisson models. `gam` is called with a list containing 2 formulae, the first specifies the response on the left hand side and the structure of the linear predictor for the Poisson parameter on the right hand side. The second is one sided, specifying the linear predictor for the probability of presence on the right hand side.

The fitted values for this family will be a two column matrix. The first column is the log of the Poisson parameter, and the second column is the complimentary log log of probability of presence.. Predictions using `predict.gam` will also produce 2 column matrices for type "link" and "response".

The null deviance computed for this model assumes that a single probability of presence and a single Poisson parameter are estimated.

For data with large areas of covariate space over which the response is zero it may be advisable to use low order penalties to avoid problems. For 1D smooths uses e.g. `s(x,m=1)` and for isotropic smooths use `Duchon.splines` in place of thin plate terms with order 1 penalties, e.g `s(x,z,m=c(1,.5))` — such smooths penalize towards constants, thereby avoiding extreme estimates when the data are uninformative.

## Value

An object inheriting from class `general.family`.

**WARNINGS**

Zero inflated models are often over-used. Having lots of zeroes in the data does not in itself imply zero inflation. Having too many zeroes \*given the model mean\* may imply zero inflation.

**Author(s)**

Simon N. Wood <simon.wood@r-project.org>

**Examples**

```
library(mgcv)
## simulate some data...
f0 <- function(x) 2 * sin(pi * x); f1 <- function(x) exp(2 * x)
f2 <- function(x) 0.2 * x^11 * (10 * (1 - x))^6 + 10 *
      (10 * x)^3 * (1 - x)^10
n <- 500;set.seed(5)
x0 <- runif(n); x1 <- runif(n)
x2 <- runif(n); x3 <- runif(n)

## Simulate probability of potential presence...
eta1 <- f0(x0) + f1(x1) - 3
p <- binomial()$linkinv(eta1)
y <- as.numeric(runif(n)<p) ## 1 for presence, 0 for absence

## Simulate y given potentially present (not exactly model fitted!)...
ind <- y>0
eta2 <- f2(x2[ind])/3
y[ind] <- rpois(exp(eta2),exp(eta2))

## Fit ZIP model...
b <- gam(list(y~s(x2)+s(x3),~s(x0)+s(x1)),family=ziplss())
b$outer.info ## check convergence

summary(b)
plot(b,pages=1)

# The nlme package

---

ACF

*Autocorrelation Function*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls` and `lme`.

### Usage

```
ACF(object, maxLag, ...)
```

### Arguments

<code>object</code>	any object from which an autocorrelation function can be obtained. Generally an object resulting from a model fit, from which residuals can be extracted.
<code>maxLag</code>	maximum lag for which the autocorrelation should be calculated.
<code>...</code>	some methods for this generic require additional arguments.

### Value

will depend on the method function used; see the appropriate documentation.

### Author(s)

José Pinheiro and Douglas Bates <Bates@stat.wisc.edu>

### References

Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994) "Time Series Analysis: Forecasting and Control", 3rd Edition, Holden-Day.

---

ACF.gls	<i>Autocorrelation Function for gls Residuals</i>
---------	---

---

Description

This method function calculates the empirical autocorrelation function for the residuals from a `gls` fit. If a grouping variable is specified in `form`, the autocorrelation values are calculated using pairs of residuals within the same group; otherwise all possible residual pairs are used. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

Usage

```
## S3 method for class 'gls'
ACF(object, maxLag, resType, form, na.action, ...)
```

Arguments

<code>object</code>	an object inheriting from class " <code>gls</code> ", representing a generalized least squares fitted model.
<code>maxLag</code>	an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the residuals.
<code>resType</code>	an optional character string specifying the type of residuals to be used. If " <code>response</code> ", the " <code>raw</code> " residuals (observed - fitted) are used; else, if " <code>pearson</code> ", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if " <code>normalized</code> ", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to " <code>pearson</code> ".
<code>form</code>	an optional one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . The time covariate must be integer valued. When a grouping factor is present in <code>form</code> , the autocorrelations are calculated using residual pairs within the same group. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>ACF.gls</code> to print an error message and terminate if there are any incomplete observations.
<code>...</code>	some methods for this generic require additional arguments.

Value

a data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fm2Dial.gls <- update(fmlDial.gls,
  weights = varPower(form = ~ pressure))

ACF(fm2Dial.gls, form = ~ 1 | Subject)
```

---

ACF.lme

---

*Autocorrelation Function for lme Residuals*

---

**Description**

This method function calculates the empirical autocorrelation function for the within-group residuals from an `lme` fit. The autocorrelation values are calculated using pairs of residuals within the innermost group level. The autocorrelation function is useful for investigating serial correlation models for equally spaced data.

**Usage**

```
## S3 method for class 'lme'
ACF(object, maxLag, resType, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.
<code>maxLag</code>	an optional integer giving the maximum lag for which the autocorrelation should be calculated. Defaults to maximum lag in the within-group residuals.

`resType` an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".

... some methods for this generic require additional arguments – not used.

### Value

a data frame with columns `lag` and `ACF` representing, respectively, the lag between residuals within a pair and the corresponding empirical autocorrelation. The returned value inherits from class `ACF`.

```

---

Alfalfa

*Split-Plot Experiment on Varieties of Alfalfa*

---

### Description

The `Alfalfa` data frame has 72 rows and 4 columns.

Format

This data frame contains the following columns:

- Variety** a factor with levels Cossack, Ladak, and Ranger
- Date** a factor with levels None S1 S20 O7
- Block** a factor with levels 1 2 3 4 5 6
- Yield** a numeric vector

Details

These data are described in Snedecor and Cochran (1980) as an example of a split-plot design. The treatment structure used in the experiment was a 3x4 full factorial, with three varieties of alfalfa and four dates of third cutting in 1943. The experimental units were arranged into six blocks, each subdivided into four plots. The varieties of alfalfa (*Cossac*, *Ladak*, and *Ranger*) were assigned randomly to the blocks and the dates of third cutting (*None*, *S1*—September 1, *S20*—September 20, and *O7*—October 7) were randomly assigned to the plots. All four dates were used on each block.

allCoef	<i>Extract Coefficients from a Set of Objects</i>
---------	---

---

Description

The extractor function is applied to each object in . . . , with the result being converted to a vector. A `map` attribute is included to indicate which pieces of the returned vector correspond to the original objects in `dots`.

Usage

```
allCoef(..., extract)
```

Arguments

- `...` objects to which `extract` will be applied. Generally these will be model components, such as `corStruct` and `varFunc` objects.
- `extract` an optional extractor function. Defaults to `coef`.

Value

a vector with all elements, generally coefficients, obtained by applying `extract` to the objects in . . . .

anova.gls

*Compare Likelihoods of Fitted Objects*

---

**Description**

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when `Terms` and `L` are `NULL`), a combination of model terms (when `Terms` is not `NULL`), or linear combinations of the model coefficients (when `L` is not `NULL`). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If `test=TRUE`, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

**Usage**

```
## S3 method for class 'glS'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
```

**Arguments**

<code>object</code>	a fitted model object inheriting from class <code>glS</code> , representing a generalized least squares fit.
<code>...</code>	other optional fitted model objects inheriting from classes <code>"glS"</code> , <code>"gnls"</code> , <code>"lm"</code> , <code>"lme"</code> , <code>"lmList"</code> , <code>"nlme"</code> , <code>"nlsList"</code> , or <code>"nls"</code> .
<code>test</code>	an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by <code>object</code> and the objects in <code>...</code> . Defaults to <code>TRUE</code> .
<code>type</code>	an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If <code>"sequential"</code> , the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if <code>"marginal"</code> , the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"sequential"</code> .
<code>adjustSigma</code>	an optional logical value. If <code>TRUE</code> and the estimation method used to obtain <code>object</code> was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is <code>TRUE</code> .

```

anova.lme

*Compare Likelihoods of Fitted Objects*

## Description

When only one fitted model object is present, a data frame with the sums of squares, numerator degrees of freedom, denominator degrees of freedom, F-values, and P-values for Wald tests for the terms in the model (when `Terms` and `L` are `NULL`), a combination of model terms (when `Terms` is not `NULL`), or linear combinations of the model coefficients (when `L` is not `NULL`). Otherwise, when multiple fitted objects are being compared, a data frame with the degrees of freedom, the (restricted) log-likelihood, the Akaike Information Criterion (AIC), and the Bayesian Information Criterion (BIC) of each object is returned. If `test=TRUE`, whenever two consecutive objects have different number of degrees of freedom, a likelihood ratio statistic, with the associated p-value is included in the returned data frame.

## Usage

```

## S3 method for class 'lme'
anova(object, ..., test, type, adjustSigma, Terms, L, verbose)
## S3 method for class 'anova.lme'
print(x, verbose, ...)

```

**Arguments**

object	an object inheriting from class "lme", representing a fitted linear mixed-effects model.
...	other optional fitted model objects inheriting from classes "gls", "gnls", "lm", "lme", "lmList", "nlme", "nlsList", or "nls".
test	an optional logical value controlling whether likelihood ratio tests should be used to compare the fitted models represented by object and the objects in ... Defaults to TRUE.
type	an optional character string specifying the type of sum of squares to be used in F-tests for the terms in the model. If "sequential", the sequential sum of squares obtained by including the terms in the order they appear in the model is used; else, if "marginal", the marginal sum of squares obtained by deleting a term from the model at a time is used. This argument is only used when a single fitted object is passed to the function. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "sequential".
adjustSigma	an optional logical value. If TRUE and the estimation method used to obtain object was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is TRUE.
Terms	an optional integer or character vector specifying which terms in the model should be jointly tested to be zero using a Wald F-test. If given as a character vector, its elements must correspond to term names; else, if given as an integer vector, its elements must correspond to the order in which terms are included in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.
L	an optional numeric vector or array specifying linear combinations of the coefficients in the model that should be tested to be zero. If given as an array, its rows define the linear combinations to be tested. If names are assigned to the vector elements (array columns), they must correspond to coefficients names and will be used to map the linear combination(s) to the coefficients; else, if no names are available, the vector elements (array columns) are assumed in the same order as the coefficients appear in the model. This argument is only used when a single fitted object is passed to the function. Default is NULL.
x	an object inheriting from class "anova.lme"
verbose	an optional logical value. If TRUE, the calling sequences for each fitted model object are printed with the rest of the output, being omitted if verbose = FALSE. Defaults to FALSE.

**Value**

a data frame inheriting from class "anova.lme".

**Note**

Likelihood comparisons are not meaningful for objects fit using restricted maximum likelihood and with different fixed effects.

---

as.matrix.corStruct

*Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix, or list of correlation matrices, associated with object.

## Usage

```

## S3 method for class 'corStruct'
as.matrix(x, ...)

```

## Arguments

<code>x</code>	an object inheriting from class " <code>corStruct</code> ", representing a correlation structure.
<code>...</code>	further arguments passed from other methods.

## Value

If the correlation structure includes a grouping factor, the returned value will be a list with components given by the correlation matrices for each group. Otherwise, the returned value will be a matrix representing the correlation structure associated with object.

as.matrix.pdMat	<i>Matrix of a pdMat Object</i>
-----------------	---------------------------------

---

## Description

This method function extracts the positive-definite matrix represented by `x`.

## Usage

```
## S3 method for class 'pdMat'
as.matrix(x, ...)
```

## Arguments

<code>x</code>	an object inheriting from class " <a href="#">pdMat</a> ", representing a positive-definite matrix.
<code>...</code>	further arguments passed from other methods.

## Value

a matrix corresponding to the positive-definite matrix represented by `x`.

`as.matrix.reStruct` *Matrices of an reStruct Object*

---

### Description

This method function extracts the positive-definite matrices corresponding to the `pdMat` elements of `object`.

### Usage

```
## S3 method for class 'reStruct'
as.matrix(x, ...)
```

### Arguments

<code>x</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>...</code>	further arguments passed from other methods.

### Value

a list with components given by the positive-definite matrices corresponding to the elements of `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

asOneFormula	<i>Combine Formulas of a Set of Objects</i>
--------------	---

---

**Description**

The names of all variables used in the formulas extracted from the objects defined in ... are converted into a single linear formula, with the variables names separated by +.

**Usage**

```
asOneFormula(..., omit)
```

**Arguments**

- ... objects, or lists of objects, from which a formula can be extracted.
- omit an optional character vector with the names of variables to be omitted from the returned formula. Defaults to c(".", "pi").

**Value**

a one-sided linear formula with all variables named in the formulas extracted from the objects in ..., except the ones listed in omit.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
asOneFormula(y ~ x + z | g, list(~ w, ~ t * sin(2 * pi)))
```

---

Assay	<i>Bioassay on Cell Culture Plate</i>
-------	---------------------------------------

---

**Description**

The Assay data frame has 60 rows and 4 columns.

**Format**

This data frame contains the following columns:

- Block** an ordered factor with levels 2 < 1 identifying the block where the wells are measured.
- sample** a factor with levels a to f identifying the sample corresponding to the well.
- dilut** a factor with levels 1 to 5 indicating the dilution applied to the well
- logDens** a numeric vector of the log-optical density

## Details

These data, courtesy of Rich Wolfe and David Lansky from Searle, Inc., come from a bioassay run on a 96-well cell culture plate. The assay is performed using a split-block design. The 8 rows on the plate are labeled A–H from top to bottom and the 12 columns on the plate are labeled 1–12 from left to right. Only the central 60 wells of the plate are used for the bioassay (the intersection of rows B–G and columns 2–11). There are two blocks in the design: Block 1 contains columns 2–6 and Block 2 contains columns 7–11. Within each block, six samples are assigned randomly to rows and five (serial) dilutions are assigned randomly to columns. The response variable is the logarithm of the optical density. The cells are treated with a compound that they metabolize to produce the stain. Only live cells can make the stain, so the optical density is a measure of the number of cells that are alive and healthy.

---

asTable

---

Convert groupedData to a matrix

---

## Description

Create a tabular representation of the response in a balanced groupedData object.

## Usage

```
asTable(object)
```

## Arguments

object                      A balanced groupedData object

## Details

A balanced groupedData object can be represented as a matrix or table of response values corresponding to the values of a primary covariate for each level of a grouping factor. This function creates such a matrix representation of the data in object.

## Value

A matrix. The data in the matrix are the values of the response. The columns correspond to the distinct values of the primary covariate and are labelled as such. The rows correspond to the distinct levels of the grouping factor and are labelled as such.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
asTable(Orthodont)

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
```

---

augPred	<i>Augmented Predictions</i>
---------	------------------------------

---

Description

Predicted values are obtained at the specified values of `primary`. If `object` has a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. If `level` has more than one element, predictions are obtained for each level of the `max(level)` grouping factor. If other covariates besides `primary` are used in the prediction model, their average (numeric covariates) or most frequent value (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

Usage

```
augPred(object, primary, minimum, maximum, length.out, ...)

## S3 method for class 'lme'
augPred(object, primary = NULL,
        minimum = min(primary), maximum = max(primary),
        length.out = 51, level = Q, ...)
```

Arguments

<code>object</code>	a fitted model object from which predictions can be extracted, using a <code>predict</code> method.
<code>primary</code>	an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate <code>object</code> (using <code>getCovariate</code> ), it will be used as <code>primary</code> .
<code>minimum</code>	an optional lower limit for the primary covariate. Defaults to <code>min(primary)</code> .
<code>maximum</code>	an optional upper limit for the primary covariate. Defaults to <code>max(primary)</code> .
<code>length.out</code>	an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
<code>level</code>	an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.
<code>...</code>	some methods for the generic may require additional arguments.

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: `original` for the observed values and `predicted` (single or no grouping factor) or `predict.groupVar` (multiple levels of grouping), with `groupVar` replaced by the actual grouping variable name (`fixed` is used for population predictions). The returned object inherits from class `"augPred"`.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

balancedGrouped	Create a groupedData object from a matrix
-----------------	---

---

**Description**

Create a `groupedData` object from a data matrix. This function can be used only with balanced data. The opposite conversion, from a `groupedData` object to a `matrix`, is done with `asTable`.

**Usage**

```
balancedGrouped(form, data, labels=NULL, units=NULL)
```

**Arguments**

<code>form</code>	A formula of the form $y \sim x \mid g$ giving the name of the response, the primary covariate, and the grouping factor.
<code>data</code>	A matrix or data frame containing the values of the response grouped according to the levels of the grouping factor (rows) and the distinct levels of the primary covariate (columns). The <code>dimnames</code> of the matrix are used to construct the levels of the grouping factor and the primary covariate.

labels	an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either label can be omitted.
units	an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either units string can be omitted.

**Value**

A balanced `groupedData` object.

**Author(s)**

Orth2 <- balancedGrouped(distance ~ age | Subject, data = OrthoMat,
  labels = list(x = "Age",
               y = "Distance from pituitary to pterygomaxillary fissure"),
  units = list(x = "(yr)", y = "(mm)"))
Orth2[ 1:10, ]      ## check the first few entries

# Pinheiro and Bates, p. 109
ergoStool.mat <- asTable(ergoStool)
balancedGrouped(effort~Type|Subject,
  data=ergoStool.mat)
```

---

bdf

*Language scores*

---

**Description**

The `bdf` data frame has 2287 rows and 25 columns of language scores from grade 8 pupils in elementary schools in The Netherlands.

**Usage**

```
data(bdf)
```

**Format**

**schoolNR** a factor denoting the school.

**pupilNR** a factor denoting the pupil.

**IQ.verb** a numeric vector of verbal IQ scores

**IQ.perf** a numeric vector of IQ scores.

**sex** Sex of the student.

**Minority** a factor indicating if the student is a member of a minority group.

**repeatgr** an ordered factor indicating if one or more grades have been repeated.

**aritPRET** a numeric vector

**classNR** a numeric vector

**aritPOST** a numeric vector

**langPRET** a numeric vector

**langPOST** a numeric vector

**ses** a numeric vector of socioeconomic status indicators.

**denomina** a factor indicating if the school is a public school, a Protestant private school, a Catholic private school, or a non-denominational private school.

**schoolSES** a numeric vector

**satiprin** a numeric vector

**natitest** a factor with levels 0 and 1

**meetings** a numeric vector

**currmeet** a numeric vector

**mixedgra** a factor indicating if the class is a mixed-grade class.

**percmينو** a numeric vector

**aritdiff** a numeric vector

**homework** a numeric vector

**classsiz** a numeric vector

**groupsiz** a numeric vector

BodyWeight

*Rat weight over time for different diets***Description**

The BodyWeight data frame has 176 rows and 4 columns.

**Format**

This data frame contains the following columns:

**weight** a numeric vector giving the body weight of the rat (grams).

**Time** a numeric vector giving the time at which the measurement is made (days).

**Rat** an ordered factor with levels 2 < 3 < 4 < 1 < 8 < 5 < 6 < 7 < 11 < 9 < 10 < 12 < 13 < 15 < 14 < 16 identifying the rat whose weight is measured.

**Diet** a factor with levels 1 to 3 indicating the diet that the rat receives.

**Details**

Hand and Crowder (1996) describe data on the body weights of rats measured over 64 days. These data also appear in Table 2.4 of Crowder and Hand (1990). The body weights of the rats (in grams) are measured on day 1 and every seven days thereafter until day 64, with an extra measurement on day 44. The experiment started several weeks before “day 1.” There are three groups of rats, each on a different diet.

Cefamandole

*Pharmacokinetics of Cefamandole***Description**

The Cefamandole data frame has 84 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor giving the subject from which the sample was drawn.

**Time** a numeric vector giving the time at which the sample was drawn (minutes post-injection).

**conc** a numeric vector giving the observed plasma concentration of cefamandole (mcg/ml).

Details

Davidian and Giltinan (1995, 1.1, p. 2) describe data obtained during a pilot study to investigate the pharmacokinetics of the drug cefamandole. Plasma concentrations of the drug were measured on six healthy volunteers at 14 time points following an intravenous dose of 15 mg/kg body weight of cefamandole.

plot(Cefamandole)
fml <- nlsList(SSbiexp, data = Cefamandole)
summary(fml)
```

Coef	Assign Values to Coefficients
------	-------------------------------

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "pdMat", "corStruct" and "varFunc" classes, "reStruct", and "modelStruct".

Usage

```
coef(object, ...) <- value
```

Arguments

- objectany object representing a fitted model, or, by default, any object with a coef component.
- ...some methods for this generic function may require additional arguments.
- valuea value to be assigned to the coefficients associated with object.

Value

will depend on the method function; see the appropriate documentation.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
## see the method function documentation
```

---

coef.corStruct	<i>Coefficients of a corStruct Object</i>
----------------	---

---

## Description

This method function extracts the coefficients associated with the correlation structure represented by `object`.

## Usage

```
## S3 method for class 'corStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'corStruct'
coef(object, ...) <- value
```

## Arguments

<code>object</code>	an object inheriting from class " <code>corStruct</code> ", representing a correlation structure.
<code>unconstrained</code>	a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the coefficients are returned in "natural", possibly constrained, form. Defaults to <code>TRUE</code> .
<code>value</code>	a vector with the replacement values for the coefficients associated with <code>object</code> . It must be a vector with the same length of <code>coef{object}</code> and must be given in unconstrained form.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

a vector with the coefficients corresponding to `object`.

## SIDE EFFECTS

On the left side of an assignment, sets the values of the coefficients of `object` to `value`. `Object` must be initialized (using `Initialize`) before new values can be assigned to its coefficients.

## Author(s)

José Pinheiro and Douglas Bates

## References

cst1 <- corARMA(p = 1, q = 1)
coef(cst1)
```

---

coef.gnls

---

*Extract gnls Coefficients*

---

**Description**

The estimated coefficients for the nonlinear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'gnls'
coef(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">gnls</a> ", representing a generalized nonlinear least squares fitted model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the estimated coefficients for the nonlinear model represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gnls](#)

**Examples**

```
fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
coef(fm1)
```

coef.lme

*Extract lme Coefficients***Description**

The estimated coefficients at level  $i$  are obtained by adding together the fixed effects estimates and the corresponding random effects estimates at grouping levels less or equal to  $i$ . The resulting estimates are returned as a data frame, with rows corresponding to groups and columns to coefficients. Optionally, the returned data frame may be augmented with covariates summarized over groups.

**Usage**

```
## S3 method for class 'lme'
coef(object, augFrame, level, data, which, FUN,
      omitGroupingFactor, subset, ...)
```

**Arguments**

object	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
augFrame	an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in <code>data</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .
level	an optional positive integer giving the level of grouping to be used in extracting the coefficients from an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
data	an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .
which	an optional positive integer or character vector specifying which columns of <code>data</code> should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .
FUN	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing <code>data</code> by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
omitGroupingFactor	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .

subset	an optional expression specifying a subset
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame inheriting from class "coef.lme" with the estimated coefficients at level `level` and, optionally, other covariates summarized over groups. The returned object also inherits from classes "ranef.lme" and "data.frame".

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

coef(fml, augFrame = TRUE)
```

---

coef.lmList	<i>Extract lmList Coefficients</i>
-------------	------------------------------------

---

**Description**

The coefficients of each `lm` object in the `object` list are extracted and organized into a data frame, with rows corresponding to the `lm` components and columns corresponding to the coefficients. Optionally, the returned data frame may be augmented with covariates summarized over the groups associated with the `lm` components.

**Usage**

```
## S3 method for class 'lmList'
coef(object, augFrame, data, which, FUN,
      omitGroupingFactor, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.
<code>augFrame</code>	an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in the data frame used to produce <code>object</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .
<code>data</code>	an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .
<code>which</code>	an optional positive integer or character vector specifying which columns of the data frame used to produce <code>object</code> should be used in the augmentation of the returned data frame. Defaults to all variables in the data.
<code>FUN</code>	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing the data by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
<code>omitGroupingFactor</code>	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame inheriting from class `"coef.lmList"` with the estimated coefficients for each `"lm"` component of `object` and, optionally, other covariates summarized over the groups corresponding to the `"lm"` components. The returned object also inherits from classes `"ranef.lmList"` and `"data.frame"`.

coef(fm1, augFrame = TRUE)
```

---

coef.modelStruct      *Extract modelStruct Object Coefficients*

---

**Description**

This method function extracts the coefficients associated with each component of the modelStruct list.

**Usage**

```
## S3 method for class 'modelStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'modelStruct'
coef(object, ...) <- value
```

**Arguments**

object	an object inheriting from class "modelStruct", representing a list of model components, such as "corStruct" and "varFunc" objects.
unconstrained	a logical value. If TRUE the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If FALSE the coefficients are returned in "natural", possibly constrained, form. Defaults to TRUE.
value	a vector with the replacement values for the coefficients associated with object. It must be a vector with the same length of coef{object} and must be given in unconstrained form.
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with all coefficients corresponding to the components of object.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of object to value. Object must be initialized (using Initialize) before new values can be assigned to its coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

  corStruct = corAR1(0.3))
coef(lms1)
```

coef.pdMat

*pdMat Object Coefficients***Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

**Usage**

```
## S3 method for class 'pdMat'
coef(object, unconstrained, ...)
## S3 replacement method for class 'pdMat'
coef(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>pdMat</code> ", representing a positive-definite matrix.
<code>unconstrained</code>	a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the upper triangular elements of the positive-definite matrix represented by <code>object</code> are returned. Defaults to <code>TRUE</code> .
<code>value</code>	a vector with the replacement values for the coefficients associated with <code>object</code> . It must be a vector with the same length of <code>coef{object}</code> and must be given in unconstrained form.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

---

coef.reStruct	<i>reStruct Object Coefficients</i>
---------------	-------------------------------------

---

**Description**

This method function extracts the coefficients associated with the positive-definite matrix represented by `object`.

**Usage**

```
## S3 method for class 'reStruct'
coef(object, unconstrained, ...)
## S3 replacement method for class 'reStruct'
coef(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">reStruct</a> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>unconstrained</code>	a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the coefficients are returned in "natural", possibly constrained, form. Defaults to <code>TRUE</code> .
<code>value</code>	a vector with the replacement values for the coefficients associated with <code>object</code> . It must be a vector with the same length of <code>coef(object)</code> and must be given in unconstrained form.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ)))
coef(rs1)
```

coef.varFunc

*varFunc Object Coefficients***Description**

This method function extracts the coefficients associated with the variance function structure represented by `object`.

**Usage**

```
## S3 method for class 'varFunc'
coef(object, unconstrained, allCoef, ...)
## S3 replacement method for class 'varIdent'
coef(object, ...) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>varFunc</code> " representing a variance function structure.
<code>unconstrained</code>	a logical value. If <code>TRUE</code> the coefficients are returned in unconstrained form (the same used in the optimization algorithm). If <code>FALSE</code> the coefficients are returned in "natural", generally constrained form. Defaults to <code>TRUE</code> .
<code>allCoef</code>	a logical value. If <code>FALSE</code> only the coefficients which may vary during the optimization are returned. If <code>TRUE</code> all coefficients are returned. Defaults to <code>FALSE</code> .
<code>value</code>	a vector with the replacement values for the coefficients associated with <code>object</code> . It must have the same length of <code>coef{object}</code> and must be given in unconstrained form. <code>Object</code> must be initialized before new values can be assigned to its coefficients.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the coefficients corresponding to `object`.

**SIDE EFFECTS**

On the left side of an assignment, sets the values of the coefficients of `object` to `value`.

**Author(s)**

José Pinheiro and Douglas Bates

```
vf1 <- varPower(1)
coef(vf1)

coef(vf1) <- 2
```

---

`collapse`*Collapse According to Groups*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Currently, only a `groupedData` method is available.

**Usage**

```
collapse(object, ...)
```

**Arguments**

<code>object</code>	an object to be collapsed, usually a data frame.
<code>...</code>	some methods for the generic may require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**[collapse.groupedData](#)**Examples**

```
## see the method function documentation
```

---

collapse.groupedData

*Collapse a groupedData Object*

---

## Description

If `object` has a single grouping factor, it is returned unchanged. Else, it is summarized by the values of the `displayLevel` grouping factor (or the combination of its values and the values of the covariate indicated in `preserve`, if any is present). The collapsed data is used to produce a new `groupedData` object, with grouping factor given by the `displayLevel` factor.

## Usage

```
## S3 method for class 'groupedData'
collapse(object, collapseLevel, displayLevel,
         outer, inner, preserve, FUN, subset, ...)
```

## Arguments

<code>object</code>	an object inheriting from class <code>groupedData</code> , generally with multiple grouping factors.
<code>collapseLevel</code>	an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
<code>displayLevel</code>	an optional positive integer or character string indicating the grouping level to use as the grouping factor for the collapsed data. Default is <code>collapseLevel</code> .
<code>outer</code>	an optional logical value or one-sided formula, indicating covariates that are outer to the <code>displayLevel</code> grouping factor. If equal to <code>TRUE</code> , the <code>displayLevel</code> element <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.
<code>inner</code>	an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.
<code>preserve</code>	an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is <code>NULL</code> , meaning that no covariates need to be preserved.
<code>FUN</code>	an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each

	non-invariant variable by group to produce the summary for that variable. If FUN is a list of functions, the names in the list should designate classes of variables in the data such as ordered, factor, or numeric. The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are mean for numeric factors, and Mode for both factor and ordered. The Mode function, defined internally in gsummary, returns the modal or most popular value of the variable. It is different from the mode function that returns the S-language mode of the variable.
subset	an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be preserved in the collapsed data. Default is NULL, meaning that all levels are used.
...	some methods for this generic require additional arguments. None are used in this method.

Value

a groupedData object with a single grouping factor given by the displayLevel grouping factor, resulting from collapsing object over the levels of the collapseLevel grouping factor.

collapse(Pixel, collapse = 1) # same as collapse(Pixel, collapse = "Dog")
```

---

compareFits	<i>Compare Fitted Objects</i>
-------------	-------------------------------

---

Description

The columns in object1 and object2 are put together in matrices which allow direct comparison of the individual elements for each object. Missing columns in either object are replaced by NAs.

Usage

```
compareFits(object1, object2, which)
```

**Arguments**

`object1, object2`  
 data frames, or matrices, with the same row names, but possibly different column names. These will usually correspond to coefficients from fitted objects with a grouping structure (e.g. `lme` and `lmList` objects).

`which`  
 an optional integer or character vector indicating which columns in `object1` and `object2` are to be used in the returned object. Defaults to all columns.

**Value**

a three-dimensional array, with the third dimension given by the number of unique column names in either `object1` or `object2`. To each column name there corresponds a matrix with as many rows as the rows in `object1` and two columns, corresponding to `object1` and `object2`. The returned object inherits from class `compareFits`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[plot.compareFits](#), [pairs.compareFits](#), [comparePred](#), [coef](#), [random.effects](#)

**Examples**

```
fm1 <- lmList(Orthodont)
fm2 <- lme(fm1)
compareFits(coef(fm1), coef(fm2))
```

---

`comparePred`

*Compare Predictions*

---

**Description**

Predicted values are obtained at the specified values of `primary` for each object. If either `object1` or `object2` have a grouping structure (i.e. `getGroups(object)` is not `NULL`), predicted values are obtained for each group. When both objects determine groups, the group levels must be the same. If other covariates besides `primary` are used in the prediction model, their group-wise averages (numeric covariates) or most frequent values (categorical covariates) are used to obtain the predicted values. The original observations are also included in the returned object.

**Usage**

```
comparePred(object1, object2, primary, minimum, maximum,
            length.out, level, ...)
```

**Arguments**

<code>object1, object2</code>	fitted model objects, from which predictions can be extracted using the <code>predict</code> method.
<code>primary</code>	an optional one-sided formula specifying the primary covariate to be used to generate the augmented predictions. By default, if a covariate can be extracted from the data used to generate the objects (using <code>getCovariate</code> ), it will be used as <code>primary</code> .
<code>minimum</code>	an optional lower limit for the primary covariate. Defaults to <code>min(primary)</code> , after <code>primary</code> is evaluated in the data used in fitting <code>object1</code> .
<code>maximum</code>	an optional upper limit for the primary covariate. Defaults to <code>max(primary)</code> , after <code>primary</code> is evaluated in the data used in fitting <code>object1</code> .
<code>length.out</code>	an optional integer with the number of primary covariate values at which to evaluate the predictions. Defaults to 51.
<code>level</code>	an optional integer specifying the desired prediction level. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Only one level can be specified. Defaults to the innermost level.
<code>...</code>	some methods for the generic may require additional arguments.

**Value**

a data frame with four columns representing, respectively, the values of the primary covariate, the groups (if `object` does not have a grouping structure, all elements will be 1), the predicted or observed values, and the type of value in the third column: the objects' names are used to classify the predicted values and `original` is used for the observed values. The returned object inherits from classes `comparePred` and `augPred`.

**Note**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[augPred](#), [getGroups](#)

**Examples**

```
fm1 <- lme(distance ~ age * Sex, data = Orthodont, random = ~ age)
fm2 <- update(fm1, distance ~ age)
comparePred(fm1, fm2, length.out = 2)
```

corAR1

*AR(1) Correlation Structure***Description**

This function is a constructor for the `corAR1` class, representing an autocorrelation structure of order 1. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corAR1(value, form, fixed)
```

**Arguments**

<code>value</code>	the value of the lag 1 autocorrelation, which must be between -1 and 1. Defaults to 0 (no autocorrelation).
<code>form</code>	a one sided formula of the form $\sim t$ , or $\sim t   g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corAR1`, representing an autocorrelation structure of order 1.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corARMA

*ARMA(p,q) Correlation Structure*

## Description

This function is a constructor for the `corARMA` class, representing an autocorrelation-moving average correlation structure of order (p, q). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corARMA(value, form, p, q, fixed)
```

**Arguments**

<code>value</code>	a vector with the values of the autoregressive and moving average parameters, which must have length $p + q$ and all elements between -1 and 1. Defaults to a vector of zeros, corresponding to uncorrelated observations.
<code>form</code>	a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>p, q</code>	non-negative integers specifying respectively the autoregressive order and the moving average order of the ARMA structure. Both default to 0.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corARMA`, representing an autocorrelation-moving average correlation structure.

corCAR1

*Continuous AR(1) Correlation Structure***Description**

This function is a constructor for the `corCAR1` class, representing an autocorrelation structure of order 1, with a continuous time covariate. Objects created using this constructor must be later initialized using the appropriate `Initialize` method.

**Usage**

```
corCAR1(value, form, fixed)
```

**Arguments**

<code>value</code>	the correlation between two observations one unit of time apart. Must be between 0 and 1. Defaults to 0.2.
<code>form</code>	a one sided formula of the form $\sim t$ , or $\sim t \mid g$ , specifying a time covariate $t$ and, optionally, a grouping factor $g$ . Covariates for this correlation structure need not be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corCAR1`, representing an autocorrelation structure of order 1, with a continuous time covariate.

```

---

corClasses	<i>Correlation Structure Classes</i>
------------	--------------------------------------

---

Description

Standard classes of correlation structures (`corStruct`) available in the `nlme` package.

Value

Available standard classes:

<code>corAR1</code>	autoregressive process of order 1.
<code>corARMA</code>	autoregressive moving average process, with arbitrary orders for the autoregressive and moving average components.
<code>corCAR1</code>	continuous autoregressive process (AR(1) process for a continuous time covariate).
<code>corCompSymm</code>	compound symmetry structure corresponding to a constant correlation.
<code>corExp</code>	exponential spatial correlation.
<code>corGaus</code>	Gaussian spatial correlation.
<code>corLin</code>	linear spatial correlation.
<code>corRatio</code>	Rational quadratics spatial correlation.
<code>corSpher</code>	spherical spatial correlation.
<code>corSymm</code>	general correlation matrix, with no additional structure.

**Note**

Users may define their own `corStruct` classes by specifying a `constructor` function and, at a minimum, methods for the functions `corMatrix` and `coef`. For examples of these functions, see the methods for classes `corSymm` and `corAR1`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

<code>corCompSymm</code>	<i>Compound Symmetry Correlation Structure</i>
--------------------------	--

---

**Description**

This function is a constructor for the `corCompSymm` class, representing a compound symmetry structure corresponding to uniform correlation. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corCompSymm(value, form, fixed)
```

**Arguments**

<code>value</code>	the correlation between any two correlated observations. Defaults to 0.
<code>form</code>	a one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corCompSymm`, representing a compound symmetry correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

corMatrix(cslCompSymm)
```

---

corExp

*Exponential Correlation Structure*

---

## Description

This function is a constructor for the "corExp" class, representing an exponential spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-r/d)$  when no nugget effect is present and  $(1 - n) \exp(-r/d)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corExp(value, form, nugget, metric, fixed)
```

## Arguments

<code>value</code>	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the exponential correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one.
--------------------	--

	Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
<code>form</code>	a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>nugget</code>	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
<code>metric</code>	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

### Value

an object of class "`corExp`", also inheriting from class "`corSpatial`", representing an exponential spatial correlation structure.

corFactor

*Factor of a Correlation Matrix***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all `corStruct` classes.

**Usage**

```
corFactor(object, ...)
```

**Arguments**

<code>object</code>	an object from which a correlation matrix can be extracted.
<code>...</code>	some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corFactor.corStruct](#), [recalc.corStruct](#)

**Examples**

```
## see the method function documentation
```

---

```
corFactor.corStruct
```

*Factor of a corStruct Object Matrix*

---

**Description**

This method function extracts a transpose inverse square-root factor, or a series of transpose inverse square-root factors, of the correlation matrix, or list of correlation matrices, represented by `object`. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This method extracts  $L^{-t}$ .

**Usage**

```
## S3 method for class 'corStruct'
corFactor(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">corStruct</a> " representing a correlation structure, which must have been initialized (using <code>Initialize</code> ).
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

If the correlation structure does not include a grouping factor, the returned value will be a vector with a transpose inverse square-root factor of the correlation matrix associated with `object` stacked column-wise. If the correlation structure includes a grouping factor, the returned value will be a vector with transpose inverse square-root factors of the correlation matrices for each group, stacked by group and stacked column-wise within each group.

**Note**

This method function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `corMatrix` method function can be used to obtain transpose inverse square-root factors in matrix form.

---

corGaus	<i>Gaussian Correlation Structure</i>
---------	---------------------------------------

---

Description

This function is a constructor for the `corGaus` class, representing a Gaussian spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $\exp(-(r/d)^2)$  when no nugget effect is present and  $(1-n)\exp(-(r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

Usage

```
corGaus(value, form, nugget, metric, fixed)
```

Arguments

value	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the Gaussian correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
form	a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corGaus`, also inheriting from class `corSpatial`, representing a Gaussian spatial correlation structure.

fm1BW.lme <- lme(weight ~ Time * Diet, BodyWeight,
               random = ~ Time)

# p. 223
fm2BW.lme <- update(fm1BW.lme, weights = varPower())
# p 246
fm3BW.lme <- update(fm2BW.lme,
                  correlation = corExp(form = ~ Time))
# p. 249
fm8BW.lme <- update(fm3BW.lme, correlation = corGaus(form = ~ Time))
```

---

corLin

---

*Linear Correlation Structure*

---

**Description**

This function is a constructor for the `corLin` class, representing a linear spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - (r/d)$  when no nugget effect is present and  $(1 - n)(1 - (r/d))$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corLin(value, form, nugget, metric, fixed)
```

## Arguments

<code>value</code>	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the linear correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized.
<code>form</code>	a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>nugget</code>	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
<code>metric</code>	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

## Value

an object of class `corLin`, also inheriting from class `corSpatial`, representing a linear spatial correlation structure.

---

corMatrix.corStruct

*Matrix of a corStruct Object*

---

## Description

This method function extracts the correlation matrix (or its transpose inverse square-root factor), or list of correlation matrices (or their transpose inverse square-root factors) corresponding to `covariate` and `object`. Letting  $\Sigma$  denote a correlation matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . When `corr = FALSE`, this method extracts  $L^{-t}$ .

## Usage

```
## S3 method for class 'corStruct'
corMatrix(object, covariate, corr, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>corStruct</code> " representing a correlation structure.
<code>covariate</code>	an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> .
<code>corr</code>	a logical value. If <code>TRUE</code> the function returns the correlation matrix, or list of correlation matrices, represented by <code>object</code> . If <code>FALSE</code> the function returns a transpose inverse square-root of the correlation matrix, or a list of transpose inverse square-root factors of the correlation matrices.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

If `covariate` is a vector (matrix), the returned value will be an array with the corresponding correlation matrix (or its transpose inverse square-root factor). If the `covariate` is a list of vectors (matrices), the returned value will be a list with the correlation matrices (or their transpose inverse square-root factors) corresponding to each component of `covariate`.

corMatrix(rs1)
```

corNatural

*General correlation in natural parameterization***Description**

This function is a constructor for the `corNatural` class, representing a general correlation structure in the “natural” parameterization, which is described under [pdNatural](#). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corNatural(value, form, fixed)
```

**Arguments**

<code>value</code>	an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when <code>object</code> is initialized (corresponding to an identity correlation structure).
<code>form</code>	a one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corNatural` representing a general correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Initialize.corNatural](#), [pdNatural](#), [summary.corNatural](#)

**Examples**

```
## covariate is observation order and grouping factor is Subject
cs1 <- corNatural(form = ~ 1 | Subject)
```

corRatio

*Rational Quadratic Correlation Structure***Description**

This function is a constructor for the `corRatio` class, representing a rational quadratic spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r$  apart is  $1/(1 + (r/d)^2)$  when no nugget effect is present and  $(1 - n)/(1 + (r/d)^2)$  when a nugget effect is assumed. Objects created using this constructor need to be later initialized using the appropriate `Initialize` method.

**Usage**

```
corRatio(value, form, nugget, metric, fixed)
```

**Arguments**

<code>value</code>	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the rational quadratic correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.
<code>form</code>	a one sided formula of the form $\sim S1 + \dots + Sp$ , or $\sim S1 + \dots + Sp \mid g$ , specifying spatial covariates $S1$ through $Sp$ and, optionally, a grouping factor $g$ . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to $\sim 1$ , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>nugget</code>	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
<code>metric</code>	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corRatio`, also inheriting from class `corSpatial`, representing a rational quadratic spatial correlation structure.

  corRatio(c(12.5, 0.2),
    form = ~ latitude + longitude,
    nugget = TRUE))
```

---

corSpatial

*Spatial Correlation Structure*

---

**Description**

This function is a constructor for the `corSpatial` class, representing a spatial correlation structure. This class is "virtual", having four "real" classes, corresponding to specific spatial correlation structures, associated with it: `corExp`, `corGaus`, `corLin`, `corRatio`, and `corSpher`. The returned object will inherit from one of these "real" classes, determined by the `type` argument, and from the "virtual" `corSpatial` class. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSpatial(value, form, nugget, type, metric, fixed)
```

**Arguments**

value	an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the spatial correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when object is initialized.
form	a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
nugget	an optional logical value indicating whether a nugget effect is present. Defaults to <code>FALSE</code> .
type	an optional character string specifying the desired type of correlation structure. Available types include "spherical", "exponential", "gaussian", "linear", and "rational". See the documentation on the functions <code>corSpher</code> , <code>corExp</code> , <code>corGaus</code> , <code>corLin</code> , and <code>corRatio</code> for a description of these correlation structures. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "spherical".
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class determined by the `type` argument and also inheriting from class `corSpatial`, representing a spatial correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

corSpher

*Spherical Correlation Structure*

---

## Description

This function is a constructor for the `corSpher` class, representing a spherical spatial correlation structure. Letting  $d$  denote the range and  $n$  denote the nugget effect, the correlation between two observations a distance  $r < d$  apart is  $1 - 1.5(r/d) + 0.5(r/d)^3$  when no nugget effect is present and  $(1 - n)(1 - 1.5(r/d) + 0.5(r/d)^3)$  when a nugget effect is assumed. If  $r \geq d$  the correlation is zero. Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

## Usage

```
corSpher(value, form, nugget, metric, fixed)
```

## Arguments

- |       |   |
|-------|---|
| value | an optional vector with the parameter values in constrained form. If <code>nugget</code> is <code>FALSE</code> , <code>value</code> can have only one element, corresponding to the "range" of the spherical correlation structure, which must be greater than zero. If <code>nugget</code> is <code>TRUE</code> , meaning that a nugget effect is present, <code>value</code> can contain one or two elements, the first being the "range" and the second the "nugget effect" (one minus the correlation between two observations taken arbitrarily close together); the first must be greater than zero and the second must be between zero and one. Defaults to <code>numeric(0)</code> , which results in a range of 90% of the minimum distance and a nugget effect of 0.1 being assigned to the parameters when <code>object</code> is initialized. |
| form  | a one sided formula of the form <code>~ S1+...+Sp</code> , or <code>~ S1+...+Sp   g</code> , specifying spatial covariates <code>S1</code> through <code>Sp</code> and, optionally, a grouping factor <code>g</code> . When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.   |

nugget	an optional logical value indicating whether a nugget effect is present. Defaults to FALSE.
metric	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
fixed	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to FALSE, in which case the coefficients are allowed to vary.

### Value

an object of class `corSpher`, also inheriting from class `corSpatial`, representing a spherical spatial correlation structure.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

```
corSpher(c(28, 0.2),
  form = ~ latitude + longitude, nugget = TRUE))
```

corSymm

*General Correlation Structure***Description**

This function is a constructor for the `corSymm` class, representing a general correlation structure. The internal representation of this structure, in terms of unconstrained parameters, uses the spherical parametrization defined in Pinheiro and Bates (1996). Objects created using this constructor must later be initialized using the appropriate `Initialize` method.

**Usage**

```
corSymm(value, form, fixed)
```

**Arguments**

<code>value</code>	an optional vector with the parameter values. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate dimension being assigned to the parameters when <code>object</code> is initialized (corresponding to an identity correlation structure).
<code>form</code>	a one sided formula of the form <code>~ t</code> , or <code>~ t   g</code> , specifying a time covariate <code>t</code> and, optionally, a grouping factor <code>g</code> . A covariate for this correlation structure must be integer valued. When a grouping factor is present in <code>form</code> , the correlation structure is assumed to apply only to observations within the same grouping level; observations with different grouping levels are assumed to be uncorrelated. Defaults to <code>~ 1</code> , which corresponds to using the order of the observations in the data as a covariate, and no groups.
<code>fixed</code>	an optional logical value indicating whether the coefficients should be allowed to vary in the optimization, or kept fixed at their initial value. Defaults to <code>FALSE</code> , in which case the coefficients are allowed to vary.

**Value**

an object of class `corSymm` representing a general correlation structure.

Covariate

---

*Assign Covariate Values*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include all "[varFunc](#)" classes.

## Usage

```
covariate(object) <- value
```

## Arguments

object	any object with a covariate component.
value	a value to be assigned to the covariate associated with object.

## Value

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

```

---

`Covariate.varFunc`    *Assign varFunc Covariate*

---

**Description**

The covariate(s) used in the calculation of the weights of the variance function represented by `object` is (are) replaced by `value`. If `object` has been initialized, `value` must have the same dimensions as `getCovariate(object)`.

**Usage**

```
## S3 replacement method for class 'varFunc'  
covariate(object) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure.
<code>value</code>	a value to be assigned to the covariate associated with <code>object</code> .

**Value**

a `varFunc` object similar to `object`, but with its `covariate` attribute replaced by `value`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getCovariate.varFunc](#)

**Examples**

```
vf1 <- varPower(1.1, form = ~age)  
covariate(vf1) <- Orthodont[["age"]]
```

---

Dialyzer	High-Flux Hemodialyzer
----------	------------------------

---

**Description**

The `Dialyzer` data frame has 140 rows and 5 columns.

**Format**

This data frame contains the following columns:

- Subject** an ordered factor with levels 10 < 8 < 2 < 6 < 3 < 5 < 9 < 7 < 1 < 4 < 17 < 20 < 11 < 12 < 16 < 13 < 14 < 18 < 15 < 19 giving the unique identifier for each subject
- QB** a factor with levels 200 and 300 giving the bovine blood flow rate (dL/min).
- pressure** a numeric vector giving the transmembrane pressure (dmHg).
- rate** the hemodialyzer ultrafiltration rate (mL/hr).
- index** index of observation within subject—1 through 7.

**Details**

Vonesh and Carter (1992) describe data measured on high-flux hemodialyzers to assess their *in vivo* ultrafiltration characteristics. The ultrafiltration rates (in mL/hr) of 20 high-flux dialyzers were measured at seven different transmembrane pressures (in dmHg). The *in vitro* evaluation of the dialyzers used bovine blood at flow rates of either 200~dL/min or 300~dL/min. The data, are also analyzed in Littell, Milliken, Stroup, and Wolfinger (1996).

Dim	Extract Dimensions from an Object
-----	-----------------------------------

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: "`corSpatial`", "`corStruct`", "`pdCompSymm`", "`pdDiag`", "`pdIdent`", "`pdMat`", and "`pdSymm`".

**Usage**

```
Dim(object, ...)
```

**Arguments**

<code>object</code>	any object for which dimensions can be extracted.
<code>...</code>	some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Note**

If `dim` allowed more than one argument, there would be no need for this generic function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
## see the method function documentation
```

---

<code>Dim.corSpatial</code>	<i>Dimensions of a corSpatial Object</i>
-----------------------------	--

---

**Description**

if `groups` is missing, it returns the `Dim` attribute of `object`; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```
## S3 method for class 'corSpatial'
Dim(object, groups, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">corSpatial</a> ", representing a spatial correlation structure.
<code>groups</code>	an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
<code>...</code>	further arguments to be passed to or from methods.

**Value**

a list with components:

N	length of groups
M	number of groups
spClass	an integer representing the spatial correlation class; 0 = user defined class, 1 = corSpher, 2 = corExp, 3 = corGaus, 4 = corLin
sumLenSq	sum of the squares of the number of observations per group
len	an integer vector with the number of observations per group
start	an integer vector with the starting position for the distance vectors in each group, beginning from zero

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[Dim](#), [Dim.corStruct](#)

**Examples**

```
Dim(corGaus(), getGroups(Orthodont))

cslARMA <- corARMA(0.4, form = ~ 1 | Subject, q = 1)
cslARMA <- Initialize(cslARMA, data = Orthodont)
Dim(cslARMA)
```

---

Dim.corStruct

*Dimensions of a corStruct Object*

---

**Description**

if groups is missing, it returns the Dim attribute of object; otherwise, calculates the dimensions associated with the grouping factor.

**Usage**

```
## S3 method for class 'corStruct'
Dim(object, groups, ...)
```

**Arguments**

object	an object inheriting from class " <a href="#">corStruct</a> ", representing a correlation structure.
groups	an optional factor defining the grouping of the observations; observations within a group are correlated and observations in different groups are uncorrelated.
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components:

N	length of groups
M	number of groups
maxLen	maximum number of observations in a group
sumLenSq	sum of the squares of the number of observations per group
len	an integer vector with the number of observations per group
start	an integer vector with the starting position for the observations in each group, beginning from zero

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

Dim.pdMat

*Dimensions of a pdMat Object*

---

**Description**

This method function returns the dimensions of the matrix represented by `object`.

**Usage**

```
## S3 method for class 'pdMat'
Dim(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">pdMat</a> ", representing a positive-definite matrix.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an integer vector with the number of rows and columns of the matrix represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

Earthquake	<i>Earthquake Intensity</i>
------------	-----------------------------

---

Description

The `Earthquake` data frame has 182 rows and 5 columns.

Format

This data frame contains the following columns:

- Quake** an ordered factor with levels 20 < 16 < 14 < 10 < 3 < 8 < 23 < 22 < 6 < 13 < 7 < 21 < 18 < 15 < 4 < 12 < 19 < 5 < 9 < 1 < 2 < 17 < 11 indicating the earthquake on which the measurements were made.
- Richter** a numeric vector giving the intensity of the earthquake on the Richter scale.
- distance** the distance from the seismological measuring station to the epicenter of the earthquake (km).
- soil** a factor with levels 0 and 1 giving the soil condition at the measuring station, either soil or rock.
- accel** maximum horizontal acceleration observed (g).

Details

Measurements recorded at available seismometer locations for 23 large earthquakes in western North America between 1940 and 1980. They were originally given in Joyner and Boore (1981); are mentioned in Brillinger (1987); and are analyzed in Davidian and Giltinan (1995).

ergoStool

*Ergometrics experiment with stool types***Description**

The ergoStool data frame has 36 rows and 3 columns.

**Format**

This data frame contains the following columns:

**effort** a numeric vector giving the effort (Borg scale) required to arise from a stool.

**Type** a factor with levels T1, T2, T3, and T4 giving the stool type.

**Subject** an ordered factor giving a unique identifier for the subject in the experiment.

**Details**

Devore (2000) cites data from an article in *Ergometrics* (1993, pp. 519-535) on “The Effects of a Pneumatic Stool and a One-Legged Stool on Lower Limb Joint Load and Muscular Activity.”

**Examples**

```
fml <-
  lme(effort ~ Type, data = ergoStool, random = ~ 1 | Subject)
anova( fml )
```

Fatigue

*Cracks caused by metal fatigue***Description**

The Fatigue data frame has 262 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Path** an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9 < 10 < 11 < 12 < 13 < 14 < 15 < 16 < 17 < 18 < 19 < 20 < 21 giving the test path (or test unit) number. The order is in terms of increasing failure time or decreasing terminal crack length.

**cycles** number of test cycles at which the measurement is made (millions of cycles).

**relLength** relative crack length (dimensionless).

## Details

These data are given in Lu and Meeker (1993) where they state “We obtained the data in Table 1 visually from figure 4.5.2 on page 242 of Bogdanoff and Kozin (1985).” The data represent the growth of cracks in metal for 21 test units. An initial notch of length 0.90 inches was made on each unit which then was subjected to several thousand test cycles. After every 10,000 test cycles the crack length was measured. Testing was stopped if the crack length exceeded 1.60 inches, defined as a failure, or at 120,000 cycles.

 fdHess

*Finite difference Hessian*

---

## Description

Evaluate an approximate Hessian and gradient of a scalar function using finite differences.

## Usage

```
fdHess(pars, fun, ..., .relStep=(.Machine$double.eps)^(1/3), minAbsPar=0)
```

## Arguments

<code>pars</code>	the numeric values of the parameters at which to evaluate the function <code>fun</code> and its derivatives.
<code>fun</code>	a function depending on the parameters <code>pars</code> that returns a numeric scalar.
<code>...</code>	Optional additional arguments to <code>fun</code>
<code>.relStep</code>	The relative step size to use in the finite differences. It defaults to the cube root of <code>.Machine\$double.eps</code>
<code>minAbsPar</code>	The minimum magnitude of a parameter value that is considered non-zero. It defaults to zero meaning that any non-zero value will be considered different from zero.

## Details

This function uses a second-order response surface design known as a Koschal design to determine the parameter values at which the function is evaluated.

## Value

A list with components

<code>mean</code>	the value of function <code>fun</code> evaluated at the parameter values <code>pars</code>
<code>gradient</code>	an approximate gradient
<code>Hessian</code>	a matrix whose upper triangle contains an approximate Hessian.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
fdHess(c(12.3, 2.34), function(x) x[1]*(1-exp(-0.4*x[2])))
```

---

fitted.glsStruct	<i>Calculate glsStruct Fitted Values</i>
------------------	--

---

**Description**

The fitted values for the linear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'glStruct'
fitted(object, glsFit, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">glStruct</a> ", representing a list of linear model components, such as <code>corStruct</code> and " <a href="#">varFunc</a> " objects.
<code>glFit</code>	an optional list with components <code>logLik</code> (log-likelihood), <code>beta</code> (coefficients), <code>sigma</code> (standard deviation for error term), <code>varBeta</code> (coefficients' covariance matrix), <code>fitted</code> (fitted values), and <code>residuals</code> (residuals). Defaults to <code>attr(object, "glFit")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the fitted values for the linear model represented by `object`.

**Note**

This method function is generally only used inside `gl`s and `fitted.gl`s.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

---

fitted.gnlsStruct     *Calculate gnlsStruct Fitted Values*

---

### Description

The fitted values for the nonlinear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'gnlsStruct'
fitted(object, ...)
```

### Arguments

<code>object</code>	an object inheriting from class " <code>gnlsStruct</code> ", representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a vector with the fitted values for the nonlinear model represented by `object`.

### Note

This method function is generally only used inside `gnls` and `fitted.gnls`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

---

fitted.lme     *Extract lme Fitted Values*

---

### Description

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

### Usage

```
## S3 method for class 'lme'
fitted(object, level, asList, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the fitted values split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

If a single level of grouping is specified in `level`, the returned value is either a list with the fitted values split by groups (`asList = TRUE`) or a vector with the fitted values (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the fitted values at different levels and the grouping factors. For a vector or data frame result the `napredict` method is applied.

**Author(s)**

---

<code>fitted.lmeStruct</code>	<i>Calculate lmeStruct Fitted Values</i>
-------------------------------	--

---

**Description**

The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ .

**Usage**

```
## S3 method for class 'lmeStruct'
fitted(object, level, conLin, lmeFit, ...)
```

**Arguments**

object	an object inheriting from class " <code>lmeStruct</code> ", representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
level	an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
conLin	an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix (X) combined with a response vector (y), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> .
lmeFit	an optional list with components <code>beta</code> and <code>b</code> containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the fitted values. Defaults to <code>attr(object, "lmeFit")</code> .
...	some methods for this generic accept other optional arguments.

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

**Note**

This method function is generally only used inside `lme` and `fitted.lme`.

`fitted.lmList`

*Extract lmList Fitted Values*

---

**Description**

The fitted values are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

**Usage**

```
## S3 method for class 'lmList'
fitted(object, subset, asList, ...)
```

**Arguments**

object	an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.
subset	an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the fitted values are to be extracted. Default is <code>NULL</code> , in which case all components are used.
asList	an optional logical value. If <code>TRUE</code> , the returned object is a list with the fitted values split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by the fitted values of each `lm` component of `object`, or a vector with the fitted values for all `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`lmList`, `residuals.lmList`

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
fitted(fm1)
```

---

`fitted.nlmeStruct`    *Calculate nlmeStruct Fitted Values*

---

**Description**

The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. The resulting values estimate the predictions at level  $i$ .

**Usage**

```
## S3 method for class 'nlmeStruct'
fitted(object, level, conLin, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>"nlmeStruct"</code> , representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects, plus attributes specifying the underlying nonlinear model and the response variable.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in extracting the fitted values from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components <code>"Xy"</code> , corresponding to a regression matrix (X) combined with a response vector (y), and <code>"logLik"</code> , corresponding to the log-likelihood of the underlying nlme model. Defaults to <code>attr(object, "conLin")</code> .
<code>...</code>	additional arguments that could be given to this method. None are used.

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the fitted values at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the fitted values at different levels.

**Note**

This method function is generally only used inside `nlme` and `fitted.nlme`.

fixed.effects

*Extract Fixed Effects*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

**Usage**

```
fixed.effects(object, ...)
fixef(object, ...)
```

**Arguments**

`object` any fitted model object from which fixed effects estimates can be extracted.  
`...` some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[fixef.lmList](#)

**Examples**

```
## see the method function documentation
```

---

<code>fixef.lmList</code>	<i>Extract lmList Fixed Effects</i>
---------------------------	-------------------------------------

---

**Description**

The average of the coefficients corresponding to the `lm` components of `object` is calculated.

**Usage**

```
## S3 method for class 'lmList'
fixef(object, ...)
```

**Arguments**

`object` an object inheriting from class "[lmList](#)", representing a list of `lm` objects with a common model.  
`...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the average of the individual `lm` coefficients in `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lmList](#), [random.effects.lmList](#)

**Examples**

```
fml <- lmList(distance ~ age | Subject, Orthodont)
fixed.effects(fml)
```

---

formula.pdBlocked    *Extract pdBlocked Formula*

---

**Description**

The formula attributes of the pdMat elements of `x` are extracted and returned as a list, in case `asList=TRUE`, or converted to a single one-sided formula when `asList=FALSE`. If the pdMat elements do not have a formula attribute, a NULL value is returned.

**Usage**

```
## S3 method for class 'pdBlocked'
formula(x, asList, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class "pdBlocked", representing a positive definite block diagonal matrix.
<code>asList</code>	an optional logical value. If TRUE, a list with the formulas for the individual block diagonal elements of <code>x</code> is returned; else, if FALSE, a one-sided formula combining all individual formulas is returned. Defaults to FALSE.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list of one-sided formulas, or a single one-sided formula, or NULL.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[pdBlocked](#), [pdMat](#)

**Examples**

```
pd1 <- pdBlocked(list(~ age, ~ Sex - 1))
formula(pd1)
formula(pd1, asList = TRUE)
```

---

formula.pdMat	<i>Extract pdMat Formula</i>
---------------	------------------------------

---

## Description

This method function extracts the formula associated with a `pdMat` object, in which the column and row names are specified.

## Usage

```
## S3 method for class 'pdMat'
formula(x, asList, ...)
```

## Arguments

<code>x</code>	an object inheriting from class " <code>pdMat</code> ", representing a positive definite matrix.
<code>asList</code>	logical. Should the <code>asList</code> argument be applied to each of the components? Never used.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

if `x` has a `formula` attribute, its value is returned, else `NULL` is returned.

## Note

Because factors may be present in `formula(x)`, the `pdMat` object needs to have access to a data frame where the variables named in the formula can be evaluated, before it can resolve its row and column names from the formula.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
pd1 <- pdSymm(~Sex*age)
formula(pd1)
```

---

<code>formula.reStruct</code>	<i>Extract reStruct Object Formula</i>
-------------------------------	--

---

### Description

This method function extracts a formula from each of the components of `x`, returning a list of formulas.

### Usage

```
## S3 method for class 'reStruct'
formula(x, asList, ...)
```

### Arguments

<code>x</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>asList</code>	logical. Should the <code>asList</code> argument be applied to each of the components?
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a list with the formulas of each component of `x`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

### Examples

```
rs1 <- reStruct(list(A = pdDiag(diag(2), ~age), B = ~1))
formula(rs1)
```

---

<code>gapply</code>	<i>Apply a Function by Groups</i>
---------------------	-----------------------------------

---

### Description

Applies the function to the distinct sets of rows of the data frame defined by groups.

### Usage

```
gapply(object, which, FUN, form, level, groups, ...)
```

**Arguments**

object	an object to which the function will be applied - usually a <code>groupedData</code> object or a <code>data.frame</code> . Must inherit from class <code>"data.frame"</code> .
which	an optional character or positive integer vector specifying which columns of object should be used with <code>FUN</code> . Defaults to all columns in object.
FUN	function to apply to the distinct sets of rows of the data frame object defined by the values of groups.
form	an optional one-sided formula that defines the groups. When this formula is given the right-hand side is evaluated in object, converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to <code>formula(object)</code> .
level	an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.
groups	an optional factor that will be used to split the rows into groups. Defaults to <code>getGroups(object, form, level)</code> .
...	optional additional arguments to the summary function <code>FUN</code> . Often it is helpful to specify <code>na.rm = TRUE</code> .

**Value**

Returns a data frame with as many rows as there are levels in the `groups` argument.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. sec. 3.4.

## Find number of non-missing "conc" observations for each Subject
gapply( Phenobarb, FUN = function(x) sum(!is.na(x$conc)) )

# Pinheiro and Bates, p. 127
table( gapply(Quinidine, "conc", function(x) sum(!is.na(x))) )
changeRecords <- gapply( Quinidine, FUN = function(frm)
  any(is.na(frm[["conc"]]) & is.na(frm[["dose"]])) )
```

Gasoline

*Refinery yield of gasoline***Description**

The Gasoline data frame has 32 rows and 6 columns.

**Format**

This data frame contains the following columns:

**yield** a numeric vector giving the percentage of crude oil converted to gasoline after distillation and fractionation

**endpoint** a numeric vector giving the temperature (degrees F) at which all the gasoline is vaporized

**Sample** an ordered factor giving the inferred crude oil sample number

**API** a numeric vector giving the crude oil gravity (degrees API)

**vapor** a numeric vector giving the vapor pressure of the crude oil (lbf/in<sup>2</sup>)

**ASTM** a numeric vector giving the crude oil 10% point ASTM—the temperature at which 10% of the crude oil has become vapor.

**Details**

Prater (1955) provides data on crude oil properties and gasoline yields. Atkinson (1985) uses these data to illustrate the use of diagnostics in multiple regression analysis. Three of the covariates—API, vapor, and ASTM—measure characteristics of the crude oil used to produce the gasoline. The other covariate — endpoint—is a characteristic of the refining process. Daniel and Wood (1980) notice that the covariates characterizing the crude oil occur in only ten distinct groups and conclude that the data represent responses measured on ten different crude oil samples.

getCovariate

*Extract Covariate from an Object***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `corSpatial`, `data.frame`, and `varFunc`.

**Usage**

```
getCovariate(object, form, data)
```

**Arguments**

object	any object with a covariate component
form	an optional one-sided formula specifying the covariate(s) to be extracted. Defaults to <code>formula(object)</code> .
data	a data frame in which to evaluate the variables defined in <code>form</code> .

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 100.

**See Also**

[getCovariate.corStruct](#), [getCovariate.data.frame](#),  
[getCovariate.varFunc](#), [getCovariateFormula](#)

**Examples**

```
## see the method function documentation
```

---

```
getCovariate.corStruct
```

*Extract corStruct Object Covariate*

---

**Description**

This method function extracts the covariate(s) associated with `object`.

**Usage**

```
## S3 method for class 'corStruct'
getCovariate(object, form, data)
```

**Arguments**

object	an object inheriting from class <code>corStruct</code> representing a correlation structure.
form	this argument is included to make the method function compatible with the generic. It will be assigned the value of <code>formula(object)</code> and should not be modified.
data	an optional data frame in which to evaluate the variables defined in <code>form</code> , in case <code>object</code> is not initialized and the covariate needs to be evaluated.

**Value**

when the correlation structure does not include a grouping factor, the returned value will be a vector or a matrix with the covariate(s) associated with `object`. If a grouping factor is present, the returned value will be a list of vectors or matrices with the covariate(s) corresponding to each grouping level.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[getCovariate](#)

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
getCovariate(cs1, data = Orthodont)
```

---

```
getCovariate.data.frame
```

*Extract Data Frame Covariate*

---

**Description**

The right hand side of `form`, stripped of any conditioning expression (i.e. an expression following a `|` operator), is evaluated in `object`.

**Usage**

```
## S3 method for class 'data.frame'
getCovariate(object, form, data)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>data.frame</code> .
<code>form</code>	an optional formula specifying the covariate to be evaluated in <code>object</code> . Defaults to <code>formula(object)</code> .
<code>data</code>	some methods for this generic require a separate data frame. Not used in this method.

**Value**

the value of the right hand side of `form`, stripped of any conditional expression, evaluated in `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getCovariateFormula](#)

**Examples**

```
getCovariate(Orthodont)
```

---

```
getCovariate.varFunc
```

*Extract varFunc Covariate*

---

**Description**

This method function extracts the covariate(s) associated with the variance function represented by `object`, if any is present.

**Usage**

```
## S3 method for class 'varFunc'
getCovariate(object, form, data)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>varFunc</code> , representing a variance function structure.
<code>form</code>	an optional formula specifying the covariate to be evaluated in <code>object</code> . Defaults to <code>formula(object)</code> .
<code>data</code>	some methods for this generic require a <code>data</code> object. Not used in this method.

**Value**

if `object` has a `covariate` attribute, its value is returned; else `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[covariate<-.varFunc](#)

**Examples**

```
vf1 <- varPower(1.1, form = ~age)
covariate(vf1) <- Orthodont[["age"]]
getCovariate(vf1)
```

---

```
getCovariateFormula
```

*Extract Covariates Formula*

---

### Description

The right hand side of `formula(object)`, without any conditioning expressions (i.e. any expressions after a `|` operator) is returned as a one-sided formula.

### Usage

```
getCovariateFormula(object)
```

### Arguments

`object`                      any object from which a formula can be extracted.

### Value

a one-sided formula describing the covariates associated with `formula(object)`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[getCovariate](#)

### Examples

```
getCovariateFormula(y ~ x | g)
getCovariateFormula(y ~ x)
```

---

```
getData
```

*Extract Data from an Object*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `gls`, `lme`, and `lmList`.

### Usage

```
getData(object)
```

### Arguments

`object`                      an object from which a data.frame can be extracted, generally a fitted model object.

## Value

will depend on the method function used; see the appropriate documentation.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[getData.gls](#), [getData.lme](#), [getData.lmList](#)

## Examples

```
## see the method function documentation
```

---

getData.gls

*Extract gls Object Data*

---

## Description

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

## Usage

```
## S3 method for class 'gls'
getData(object)
```

## Arguments

`object` an object inheriting from class `gls`, representing a generalized least squares fitted linear model.

## Value

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[gls](#), [getData](#)

## Examples

```
fml1 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
            correlation = corAR1(form = ~ 1 | Mare))
getData(fml1)
```

---

getData.lme	<i>Extract lme Object Data</i>
-------------	--------------------------------

---

## Description

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

## Usage

```
## S3 method for class 'lme'
getData(object)
```

## Arguments

<code>object</code>	an object inheriting from class <code>lme</code> , representing a linear mixed-effects fitted model.
---------------------	--

## Value

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

Note that as from version 3.1-102, this only omits rows omitted in the fit if `na.action = na.omit`, and does not omit at all if `na.action = na.exclude`. That is generally what is wanted for plotting, the main use of this function.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

## Examples

```
fm1 <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), data = Ovary,
          random = ~ sin(2*pi*Time))
getData(fm1)
```

---

getData.lmList	<i>Extract lmList Object Data</i>
----------------	-----------------------------------

---

## Description

If present in the calling sequence used to produce `object`, the data frame used to fit the model is obtained.

## Usage

```
## S3 method for class 'lmList'
getData(object)
```

## Arguments

<code>object</code>	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
---------------------	---

## Value

if a `data` argument is present in the calling sequence that produced `object`, the corresponding data frame (with `na.action` and `subset` applied to it, if also present in the call that produced `object`) is returned; else, `NULL` is returned.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

## Examples

```
fml <- lmList(distance ~ age | Subject, Orthodont)
getData(fml)
```

---

getGroups	<i>Extract Grouping Factors from an Object</i>
-----------	--

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `corStruct`, `data.frame`, `gls`, `lme`, `lmList`, and `varFunc`.

## Usage

```
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	any object
<code>form</code>	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> .
<code>level</code>	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting.
<code>data</code>	a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods.
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

```
getGroups.corStruct
```

*Extract corStruct Groups*

---

**Description**

This method function extracts the grouping factor associated with `object`, if any is present.

**Usage**

```
## S3 method for class 'corStruct'
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>corStruct</code> representing a correlation structure.
<code>form</code>	this argument is included to make the method function compatible with the generic. It will be assigned the value of <code>formula(object)</code> and should not be modified.
<code>level</code>	this argument is included to make the method function compatible with the generic and is not used.
<code>data</code>	an optional data frame in which to evaluate the variables defined in <code>form</code> , in case <code>object</code> is not initialized and the grouping factor needs to be evaluated.
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

**Value**

if a grouping factor is present in the correlation structure represented by `object`, the function returns the corresponding factor vector; else the function returns `NULL`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getGroups](#)

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
getGroups(cs1, data = Orthodont)
```

---

```
getGroups.data.frame
```

*Extract Groups from a Data Frame*

---

**Description**

Each variable named in the expression after the `|` operator on the right hand side of `form` is evaluated in `object`. If more than one variable is indicated in `level` they are combined into a data frame; else the selected variable is returned as a vector. When multiple grouping levels are defined in `form` and `level > 1`, the levels of the returned factor are obtained by pasting together the levels of the grouping factors of level greater or equal to `level`, to ensure their uniqueness.

**Usage**

```
## S3 method for class 'data.frame'
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>data.frame</code> .
<code>form</code>	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> .
<code>level</code>	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. Defaults to all levels of nesting.
<code>data</code>	unused
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, from outer to inner, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

getGroups.gls

---

*Extract gls Object Groups*

---

**Description**

If present, the grouping factor associated to the correlation structure for the linear model represented by `object` is extracted.

**Usage**

```
## S3 method for class 'gls'
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>gls</code> , representing a generalized least squares fitted linear model.
<code>form</code>	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.
<code>level</code>	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
<code>data</code>	a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.

**Value**

if the linear model represented by `object` incorporates a correlation structure and the corresponding `corStruct` object has a grouping factor, a vector with the group values is returned; else, `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

getGroups(fml)
```

---

`getGroups.lme`

*Extract lme Object Groups*

---

**Description**

The grouping factors corresponding to the linear mixed-effects model represented by `object` are extracted. If more than one level is indicated in `level`, the corresponding grouping factors are combined into a data frame; else the selected grouping factor is returned as a vector.

**Usage**

```
## S3 method for class 'lme'
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.
<code>form</code>	this argument is included to make the method function compatible with the generic and is ignored in this method.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be extracted from <code>object</code> . Defaults to the highest or innermost level of grouping.
<code>data</code>	unused
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

**Value**

either a data frame with columns given by the grouping factors indicated in `level`, or, when a single level is requested, a factor representing the selected grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

`getGroups.lmList`      *Extract lmList Object Groups*

---

**Description**

The grouping factor determining the partitioning of the observations used to produce the `lm` components of `object` is extracted.

**Usage**

```
## S3 method for class 'lmList'
getGroups(object, form, level, data, sep)
```

**Arguments**

object	an object inheriting from class <code>lmList</code> , representing a list of <code>lm</code> objects with a common model.
form	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.
level	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
data	a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.
sep	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.

**Value**

a vector with the grouping factor corresponding to the `lm` components of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[lmList](#)

**Examples**

```
fml <- lmList(distance ~ age | Subject, Orthodont)
getGroups(fml)
```

---

`getGroups.varFunc`    *Extract varFunc Groups*

---

**Description**

This method function extracts the grouping factor associated with the variance function represented by `object`, if any is present.

**Usage**

```
## S3 method for class 'varFunc'
getGroups(object, form, level, data, sep)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>varFunc</code> , representing a variance function structure.
<code>form</code>	an optional formula with a conditioning expression on its right hand side (i.e. an expression involving the <code> </code> operator). Defaults to <code>formula(object)</code> . Not used.
<code>level</code>	a positive integer vector with the level(s) of grouping to be used when multiple nested levels of grouping are present. This argument is optional for most methods of this generic function and defaults to all levels of nesting. Not used.
<code>data</code>	a data frame in which to interpret the variables named in <code>form</code> . Optional for most methods. Not used.
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> . Not used.

**Value**

if `object` has a `groups` attribute, its value is returned; else `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varPower(form = ~ age | Sex)
vf1 <- Initialize(vf1, Orthodont)
getGroups(vf1)
```

---

`getGroupsFormula`      *Extract Grouping Formula*

---

**Description**

The conditioning expression associated with `formula(object)` (i.e. the expression after the `|` operator) is returned either as a named list of one-sided formulas, or a single one-sided formula, depending on the value of `asList`. The components of the returned list are ordered from outermost to innermost level and are named after the grouping factor expression.

**Usage**

```
getGroupsFormula(object, asList, sep)
```

**Arguments**

<code>object</code>	any object from which a formula can be extracted.
<code>asList</code>	an optional logical value. If <code>TRUE</code> the returned value will be a list of formulas; else, if <code>FALSE</code> the returned value will be a one-sided formula. Defaults to <code>FALSE</code> .
<code>sep</code>	character, the separator to use between group levels when multiple levels are collapsed. The default is <code>'/'</code> .

**Value**

a one-sided formula, or a list of one-sided formulas, with the grouping structure associated with `formula(object)`. If no conditioning expression is present in `formula(object)` a NULL value is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

getGroupsFormula(y ~ x | g1/g2)
```

---

getResponse	<i>Extract Response Variable from an Object</i>
-------------	---

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `data.frame`, `gls`, `lme`, and `lmList`.

**Usage**

```
getResponse(object, form)
```

**Arguments**

<code>object</code>	any object
<code>form</code>	an optional two-sided formula. Defaults to <code>formula(object)</code> .

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[getResponseFormula](#)

**Examples**

```
getResponse(Orthodont)
```

---

```
getResponseFormula
```

*Extract Formula Specifying Response Variable*

---

### Description

The left hand side of `formula{object}` is returned as a one-sided formula.

### Usage

```
getResponseFormula(object)
```

### Arguments

`object` any object from which a formula can be extracted.

### Value

a one-sided formula with the response variable associated with `formula{object}`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[getResponse](#)

### Examples

```
getResponseFormula(y ~ x | g)
```

---

```
getVarCov
```

*Extract variance-covariance matrix*

---

### Description

Extract the variance-covariance matrix from a fitted model, such as a mixed-effects model.

### Usage

```
getVarCov(obj, ...)
## S3 method for class 'lme'
getVarCov(obj, individuals,
  type = c("random.effects", "conditional", "marginal"), ...)
## S3 method for class 'gls'
getVarCov(obj, individual = 1, ...)
```

**Arguments**

<code>obj</code>	A fitted model. Methods are available for models fit by <a href="#">lme</a> and by <a href="#">gls</a>
<code>individuals</code>	For models fit by <a href="#">lme</a> a vector of levels of the grouping factor can be specified for the conditional or marginal variance-covariance matrices.
<code>individual</code>	For models fit by <a href="#">gls</a> the only type of variance-covariance matrix provided is the marginal variance-covariance of the responses by group. The optional argument <code>individual</code> specifies the group of responses.
<code>type</code>	For models fit by <a href="#">lme</a> the <code>type</code> argument specifies the type of variance-covariance matrix, either <code>"random.effects"</code> for the random-effects variance-covariance (the default), or <code>"conditional"</code> for the conditional variance-covariance of the responses or <code>"marginal"</code> for the the marginal variance-covariance of the responses.
<code>...</code>	Optional arguments for some methods, as described above

**Value**

A variance-covariance matrix or a list of variance-covariance matrices.

**Author(s)**

getVarCov(fml)
getVarCov(fml, individual = "F01", type = "marginal")
getVarCov(fml, type = "conditional")
fm2 <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
          correlation = corAR1(form = ~ 1 | Mare))
getVarCov(fm2)
```

---

gls

---

*Fit Linear Model Using Generalized Least Squares*

---

**Description**

This function fits a linear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gls(model, data, correlation, weights, subset, method, na.action,
     control, verbose)
## S3 method for class 'gls'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

<code>object</code>	an object inheriting from class "gls", representing a generalized least squares fitted linear model.
<code>model</code>	a two-sided linear formula object describing the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right.
<code>model.</code>	Changes to the model – see <a href="#">update.formula</a> for details.
<code>data</code>	an optional data frame containing the variables named in <code>model</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>gls</code> is called.
<code>correlation</code>	an optional <a href="#">corStruct</a> object describing the within-group correlation structure. See the documentation of <a href="#">corClasses</a> for a description of the available <code>corStruct</code> classes. If a grouping variable is to be used, it must be specified in the <code>form</code> argument to the <code>corStruct</code> constructor. Defaults to <code>NULL</code> , corresponding to uncorrelated errors.
<code>weights</code>	an optional <a href="#">varFunc</a> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <a href="#">varFixed</a> , corresponding to fixed variance weights. See the documentation on <a href="#">varClasses</a> for a description of the available <a href="#">varFunc</a> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic errors.
<code>subset</code>	an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <a href="#">na.fail</a> ) causes <code>gls</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <a href="#">glsControl</a> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.
<code>evaluate</code>	If <code>TRUE</code> evaluate the new call else return the call.

**Value**

an object of class "gls" representing the linear model fit. Generic functions such as `print`, `plot`, and `summary` have methods to show the results of the fit. See [glsObject](#) for the components of the fit. The functions [resid](#), [coef](#) and [fitted](#), can be used to extract some of its components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

# variance increases as a power of the absolute fitted values
fm2 <- update(fm1, weights = varPower())
```

---

`glsControl`

*Control Values for gls Fit*

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gls` function.

## Usage

```
glsControl(maxIter, msMaxIter, tolerance, msTol, msVerbose,
           singular.ok, returnObject, apVar, .relStep,
           opt=c("nlminb", "optim"), optimMethod,
           minAbsParApVar, natural)
```

**Arguments**

<code>maxIter</code>	maximum number of iterations for the <code>gls</code> optimization algorithm. Default is 50.
<code>msMaxIter</code>	maximum number of iterations for the optimization step inside the <code>gls</code> optimization. Default is 50.
<code>tolerance</code>	tolerance for the convergence criterion in the <code>gls</code> algorithm. Default is 1e-6.
<code>msTol</code>	tolerance for the convergence criterion of the first outer iteration when <code>optim</code> is used. Default is 1e-7.
<code>msVerbose</code>	a logical value passed as the <code>trace</code> argument to <code>ms</code> (see documentation on that function). Default is <code>FALSE</code> .
<code>singular.ok</code>	a logical value indicating whether non-estimable coefficients (resulting from linear dependencies among the columns of the regression matrix) should be allowed. Default is <code>FALSE</code> .
<code>returnObject</code>	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is <code>FALSE</code> .
<code>apVar</code>	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is <code>TRUE</code> .
<code>.relStep</code>	relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .
<code>opt</code>	the optimizer to be used, either <code>"nlminb"</code> (the current default) or <code>"optim"</code> (the previous default).
<code>optimMethod</code>	character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .
<code>minAbsParApVar</code>	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
<code>natural</code>	logical. Should the natural parameterization be used for the approximate variance calculations? Default is <code>TRUE</code> .

**Value**

a list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`gls`

**Examples**

```
# decrease the maximum number iterations in the optimization call and
# request that information on the evolution of the ms iterations be printed
glsControl(msMaxIter = 20, msVerbose = TRUE)
```

glsObject

*Fitted gls Object***Description**

An object returned by the `gls` function, inheriting from class "gls" and representing a generalized least squares fitted linear model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate "gls" object.

<code>apVar</code>	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gls</code> , this component is equal to <code>NULL</code> .
<code>call</code>	a list containing an image of the <code>gls</code> call that produced the object.
<code>coefficients</code>	a vector with the estimated linear model coefficients.
<code>contrasts</code>	a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations in the data and <code>p</code> - the number of coefficients in the linear model.
<code>fitted</code>	a vector with the fitted values..
<code>glsStruct</code>	an object inheriting from class <code>glsStruct</code> , representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>groups</code>	a vector with the correlation structure grouping factor, if any is present.
<code>logLik</code>	the log-likelihood at convergence.
<code>method</code>	the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
<code>numIter</code>	the number of iterations used in the iterative algorithm.
<code>residuals</code>	a vector with the residuals.
<code>sigma</code>	the estimated residual standard error.
<code>varBeta</code>	an approximate covariance matrix of the coefficients estimates.

`gls`, `glsStruct`

glsStruct

*Generalized Least Squares Structure***Description**

A generalized least squares structure is a list of model components representing different sets of parameters in the linear model. A `glsStruct` may contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `glsStruct` list.

**Usage**

```
glsStruct(corStruct, varStruct)
```

**Arguments**

`corStruct` an optional `corStruct` object, representing a correlation structure. Default is `NULL`.

`varStruct` an optional `varFunc` object, representing a variance function structure. Default is `NULL`.

**Value**

a list of model variance-covariance components determining the parameters to be estimated for the associated linear model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[corClasses](#), [gls](#), [residuals.glsStruct](#), [varFunc](#)

**Examples**

```

Glucose

*Glucose levels over time***Description**

The `Glucose` data frame has 378 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor with levels 6 < 2 < 3 < 5 < 1 < 4

**Time** a numeric vector

**conc** a numeric vector of glucose levels

**Meal** an ordered factor with levels 2am < 6am < 10am < 2pm < 6pm < 10pm

**Source**

Hand, D. and Crowder, M. (1996), *Practical Longitudinal Data Analysis*, Chapman and Hall, London.

---

Glucose2

*Glucose Levels Following Alcohol Ingestion*

---

**Description**

The Glucose2 data frame has 196 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** a factor with levels 1 to 7 identifying the subject whose glucose level is measured.

**Date** a factor with levels 1 2 indicating the occasion in which the experiment was conducted.

**Time** a numeric vector giving the time since alcohol ingestion (in min/10).

**glucose** a numeric vector giving the blood glucose level (in mg/dl).

**Details**

Hand and Crowder (Table A.14, pp. 180-181, 1996) describe data on the blood glucose levels measured at 14 time points over 5 hours for 7 volunteers who took alcohol at time 0. The same experiment was repeated on a second date with the same subjects but with a dietary additive used for all subjects.

---

gnls

*Fit Nonlinear Model Using Generalized Least Squares*

---

**Description**

This function fits a nonlinear model using generalized least squares. The errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
gnls(model, data, params, start, correlation, weights, subset,  
      na.action, naPattern, control, verbose)
```

**Arguments**

<code>model</code>	a two-sided formula object describing the model, with the response on the left of a <code>~</code> operator and a nonlinear expression involving parameters and covariates on the right. If <code>data</code> is given, all names used in the formula should be defined as parameters or variables in the data frame.
<code>data</code>	an optional data frame containing the variables named in <code>model</code> , <code>correlation</code> , <code>weights</code> , <code>subset</code> , and <code>naPattern</code> . By default the variables are taken from the environment from which <code>gnls</code> is called.
<code>params</code>	an optional two-sided linear formula of the form $p_1 + \dots + p_n \sim x_1 + \dots + x_m$ , or list of two-sided formulas of the form $p_1 \sim x_1 + \dots + x_m$ , with possibly different models for each parameter. The $p_1, \dots, p_n$ represent parameters included on the right hand side of <code>model</code> and $x_1 + \dots + x_m$ define a linear model for the parameters (when the left hand side of the formula contains several parameters, they are all assumed to follow the same linear model described by the right hand side expression). A 1 on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s). By default, the parameters are obtained from the names of <code>start</code> .
<code>start</code>	an optional named list, or numeric vector, with the initial values for the parameters in <code>model</code> . It can be omitted when a <code>selfStarting</code> function is used in <code>model</code> , in which case the starting estimates will be obtained from a single call to the <code>nls</code> function.
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. If a grouping variable is to be used, it must be specified in the <code>form</code> argument to the <code>corStruct</code> constructor. Defaults to <code>NULL</code> , corresponding to uncorrelated errors.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic errors.
<code>subset</code>	an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>gnls</code> to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>gnlsControl</code> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object of class `gnls`, also inheriting from class `gls`, representing the nonlinear model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `gnlsObject` for the components of the fit. The functions `resid`, `coef`, and `fitted` can be used to extract some of its components.

---

`gnlsControl`

*Control Values for gnls Fit*

---

**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `gnls` function.

**Usage**

```
gnlsControl(maxIter, nlsMaxIter, msMaxIter, minScale, tolerance,
            nlsTol, msTol, returnObject, msVerbose,
            apVar, .relStep,
            opt = c("nlminb", "optim"), optimMethod,
            minAbsParApVar)
```

**Arguments**

<code>maxIter</code>	maximum number of iterations for the <code>gnls</code> optimization algorithm. Default is 50.
<code>nlsMaxIter</code>	maximum number of iterations for the <code>nls</code> optimization step inside the <code>gnls</code> optimization. Default is 7.
<code>msMaxIter</code>	maximum number of iterations for the <code>ms</code> optimization step inside the <code>gnls</code> optimization. Default is 50.
<code>minScale</code>	minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the <code>nls</code> step. Default 0.001.
<code>tolerance</code>	tolerance for the convergence criterion in the <code>gnls</code> algorithm. Default is 1e-6.
<code>nlsTol</code>	tolerance for the convergence criterion in <code>nls</code> step. Default is 1e-3.
<code>msTol</code>	tolerance for the convergence criterion of the first outer iteration when <code>optim</code> is used. Default is 1e-7.
<code>returnObject</code>	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is FALSE.
<code>msVerbose</code>	a logical value passed as the <code>trace</code> argument to <code>ms</code> (see documentation on that function). Default is FALSE.
<code>apVar</code>	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is TRUE.
<code>.relStep</code>	relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .
<code>opt</code>	the optimizer to be used, either <code>"nlminb"</code> (the current default) or <code>"optim"</code> (the previous default).
<code>optimMethod</code>	character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .
<code>minAbsParApVar</code>	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.

**Value**

a list with components for each of the possible arguments.

gnlsObject

*Fitted gnls Object***Description**

An object returned by the `gnls` function, inheriting from class `gnls` and also from class `gls`, and representing a generalized nonlinear least squares fitted model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `plot`, `predict`, `print`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `gnls` object.

<code>apVar</code>	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>gnls</code> , this component is equal to <code>NULL</code> .
<code>call</code>	a list containing an image of the <code>gnls</code> call that produced the object.
<code>coefficients</code>	a vector with the estimated nonlinear model coefficients.
<code>contrasts</code>	a list with the contrasts used to represent factors in the model formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the model fit, including the components <code>N</code> - the number of observations used in the fit and <code>p</code> - the number of coefficients in the nonlinear model.
<code>fitted</code>	a vector with the fitted values.
<code>modelStruct</code>	an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>groups</code>	a vector with the correlation structure grouping factor, if any is present.
<code>logLik</code>	the log-likelihood at convergence.
<code>numIter</code>	the number of iterations used in the iterative algorithm.
<code>plist</code>	
<code>pmap</code>	
<code>residuals</code>	a vector with the residuals.
<code>sigma</code>	the estimated residual standard error.
<code>varBeta</code>	an approximate covariance matrix of the coefficients estimates.

gnlsStruct	<i>Generalized Nonlinear Least Squares Structure</i>
------------	--

---

### Description

A generalized nonlinear least squares structure is a list of model components representing different sets of parameters in the nonlinear model. A `gnlsStruct` may contain `corStruct` and `varFunc` objects. NULL arguments are not included in the `gnlsStruct` list.

### Usage

```
gnlsStruct(corStruct, varStruct)
```

### Arguments

<code>corStruct</code>	an optional <code>corStruct</code> object, representing a correlation structure. Default is NULL.
<code>varStruct</code>	an optional <code>varFunc</code> object, representing a variance function structure. Default is NULL.

### Value

a list of model variance-covariance components determining the parameters to be estimated for the associated nonlinear model.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[gnls](#), [corClasses](#), [residuals.gnlsStruct](#) [varFunc](#)

### Examples

```
gnls1 <- gnlsStruct(corAR1(), varPower())
```

---

groupedData	<i>Construct a groupedData Object</i>
-------------	---------------------------------------

---

### Description

An object of the `groupedData` class is constructed from the formula and data by attaching the formula as an attribute of the data, along with any of `outer`, `inner`, `labels`, and `units` that are given. If `order.groups` is TRUE the grouping factor is converted to an ordered factor with the ordering determined by FUN. Depending on the number of grouping levels and the type of primary covariate, the returned object will be of one of three classes: `nfnGroupedData` - numeric covariate, single level of nesting; `nffGroupedData` - factor covariate, single level of nesting; and `nmGroupedData` - multiple levels of nesting. Several modeling and plotting functions can use the formula stored with a `groupedData` object to construct default plots and models.

**Usage**

```
groupedData(formula, data, order.groups, FUN, outer, inner,
  labels, units)
## S3 method for class 'groupedData'
update(object, formula, data, order.groups, FUN,
  outer, inner, labels, units, ...)
```

**Arguments**

- |              |  |
|--------------|--|
| object       | an object inheriting from class <code>groupedData</code> .   |
| formula      | a formula of the form <code>resp ~ cov   group</code> where <code>resp</code> is the response, <code>cov</code> is the primary covariate, and <code>group</code> is the grouping factor. The expression <code>1</code> can be used for the primary covariate when there is no other suitable candidate. Multiple nested grouping factors can be listed separated by the <code>/</code> symbol as in <code>fact1/fact2</code> . In an expression like this the <code>fact2</code> factor is nested within the <code>fact1</code> factor.  |
| data         | a data frame in which the expressions in <code>formula</code> can be evaluated. The resulting <code>groupedData</code> object will consist of the same data values in the same order but with additional attributes.   |
| order.groups | an optional logical value, or list of logical values, indicating if the grouping factors should be converted to ordered factors according to the function <code>FUN</code> applied to the response from each group. If multiple levels of grouping are present, this argument can be either a single logical value (which will be repeated for all grouping levels) or a list of logical values. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). Ordering within a level of grouping is done within the levels of the grouping factors which are outer to it. Changing the grouping factor to an ordered factor does not affect the ordering of the rows in the data frame but it does affect the order of the panels in a trellis display of the data or models fitted to the data. Defaults to <code>TRUE</code> .  |
| FUN          | an optional summary function that will be applied to the values of the response for each level of the grouping factor, when <code>order.groups = TRUE</code> , to determine the ordering. Defaults to the <code>max</code> function.   |
| outer        | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are outer to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. When plotting a <code>groupedData</code> object, the argument <code>outer = TRUE</code> causes the panels to be determined by the <code>outer</code> formula. The points within the panels are associated by level of the grouping factor. Defaults to <code>NULL</code> , meaning that no outer covariates are present. |
| inner        | an optional one-sided formula, or list of one-sided formulas, indicating covariates that are inner to the grouping factor(s). If multiple levels of grouping are present, this argument can be either a single one-sided formula, or a list of one-sided formulas. If no names are assigned to the list elements, they are assumed in the same order as the group levels (outermost to innermost grouping). An   |

	inner covariate can change within the sets of rows defined by the grouping factor. An inner formula can be used to associate points in a plot of a groupedData object. Defaults to <code>NULL</code> , meaning that no inner covariates are present.
<code>labels</code>	an optional list of character strings giving labels for the response and the primary covariate. The label for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either label can be omitted.
<code>units</code>	an optional list of character strings giving the units for the response and the primary covariate. The units string for the primary covariate is named <code>x</code> and that for the response is named <code>y</code> . Either units string can be omitted.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object of one of the classes `nfnGroupedData`, `nffGroupedData`, or `nmGroupedData`, and also inheriting from classes `groupedData` and `data.frame`.

**Examples**

```
Orth.new <- # create a new copy of the groupedData object
  groupedData( distance ~ age | Subject,
               data = as.data.frame( Orthodont ),
               FUN = mean,
               outer = ~ Sex,
               labels = list( x = "Age",
                             y = "Distance from pituitary to pterygomaxillary fissure" ),
               units = list( x = "(yr)", y = "(mm)" ) )

## Not run:
plot( Orth.new )           # trellis plot by Subject

## End(Not run)
formula( Orth.new )       # extractor for the formula
gsummary( Orth.new )      # apply summary by Subject
fml <- lme( Orth.new )    # fixed and groups formulae extracted from object
Orthodont2 <- update(Orthodont, FUN = mean)
```

gsummary

*Summarize by Groups***Description**

Provide a summary of the variables in a data frame by groups of rows. This is most useful with a `groupedData` object to examine the variables by group.

**Usage**

```
gsummary(object, FUN, omitGroupingFactor, form, level,
         groups, invariantsOnly, ...)
```

**Arguments**

- |                                 |  |
|---------------------------------|--|
| <code>object</code>             | an object to be summarized - usually a <code>groupedData</code> object or a <code>data.frame</code> .  |
| <code>FUN</code>                | an optional summary function or a list of summary functions to be applied to each variable in the frame. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>groups</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable. |
| <code>omitGroupingFactor</code> | an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary but the levels of the grouping factor will continue to be used as the row names for the data frame that is produced by the summary. Defaults to <code>FALSE</code> .  |
| <code>form</code>               | an optional one-sided formula that defines the groups. When this formula is given, the right-hand side is evaluated in <code>object</code> , converted to a factor if necessary, and the unique levels are used to define the groups. Defaults to <code>formula(object)</code> .   |
| <code>level</code>              | an optional positive integer giving the level of grouping to be used in an object with multiple nested grouping levels. Defaults to the highest or innermost level of grouping.  |
| <code>groups</code>             | an optional factor that will be used to split the rows into groups. Defaults to <code>getGroups(object, form, level)</code> .  |
| <code>invariantsOnly</code>     | an optional logical value. When <code>TRUE</code> only those covariates that are invariant within each group will be summarized. The summary value for the group is always the unique value taken on by that covariate within the group. The columns in the summary are of the same class as the corresponding columns in <code>object</code> .  |

By definition, the grouping factor itself must be an invariant. When combined with `omitGroupingFactor = TRUE`, this option can be used to discover if there are invariant covariates in the data frame. Defaults to `FALSE`.

... optional additional arguments to the summary functions that are invoked on the variables by group. Often it is helpful to specify `na.rm = TRUE`.

### Value

A `data.frame` with one row for each level of the grouping factor. The number of columns is at most the number of columns in `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

## gsummary with invariantsOnly = TRUE and omitGroupingFactor = TRUE
## determines whether there are covariates like Sex that are invariant
## within the repeated observations on the same Subject.
gsummary(Orthodont, inv = TRUE, omit = TRUE)
```

---

Gun

*Methods for firing naval guns*

---

### Description

The Gun data frame has 36 rows and 4 columns.

### Format

This data frame contains the following columns:

**rounds** a numeric vector

**Method** a factor with levels M1 M2

**Team** an ordered factor with levels T1S < T3S < T2S < T1A < T2A < T3A < T1H < T3H < T2H

**Physique** an ordered factor with levels Slight < Average < Heavy

### Details

Hicks (p.180, 1993) reports data from an experiment on methods for firing naval guns. Gunners of three different physiques (slight, average, and heavy) tested two firing methods. Both methods were tested twice by each of nine teams of three gunners with identical physique. The response was the number of rounds fired per minute.

**Source**

IGF

*Radioimmunoassay of IGF-I Protein***Description**

The IGF data frame has 237 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Lot** an ordered factor giving the radioactive tracer lot.

**age** a numeric vector giving the age (in days) of the radioactive tracer.

**conc** a numeric vector giving the estimated concentration of IGF-I protein (ng/ml)

**Details**

Davidian and Giltinan (1995) describe data obtained during quality control radioimmunoassays for ten different lots of radioactive tracer used to calibrate the Insulin-like Growth Factor (IGF-I) protein concentration measurements.

Initialize

*Initialize Object***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `lmeStruct`, `reStruct`, and `varFunc`.

**Usage**

```
Initialize(object, data, ...)
```

**Arguments**

<code>object</code>	any object requiring initialization, e.g. "plug-in" structures such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>data</code>	a data frame to be used in the initialization procedure.
<code>...</code>	some methods for this generic function require additional arguments.

**Value**

an initialized object with the same class as `object`. Changes introduced by the initialization procedure will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

`Initialize.corStruct`, `Initialize.lmeStruct`, `Initialize.glsStruct`,  
`Initialize.varFunc`, `isInitialized`

**Examples**

```
## see the method function documentation
```

---

```
Initialize.corStruct
```

*Initialize corStruct Object*

---

**Description**

This method initializes `object` by evaluating its associated covariate(s) and grouping factor, if any is present, in `data`, calculating various dimensions and constants used by optimization algorithms involving `corStruct` objects (see the appropriate `Dim` method documentation), and assigning initial values for the coefficients in `object`, if none were present.

**Usage**

```
## S3 method for class 'corStruct'
Initialize(object, data, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>corStruct</code> " representing a correlation structure.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>...</code>	this argument is included to make this method compatible with the generic.

**Value**

an initialized object with the same class as `object` representing a correlation structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

[Dim.corStruct](#)

**Examples**

```
cs1 <- corAR1(form = ~ 1 | Subject)
cs1 <- Initialize(cs1, data = Orthodont)
```

---

Initialize.glsStruct

*Initialize a glsStruct Object*

---

**Description**

The individual linear model components of the `glsStruct` list are initialized.

**Usage**

```
## S3 method for class 'glsStruct'
Initialize(object, data, control, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">glsStruct</a> ", representing a list of linear model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>control</code>	an optional list with control parameters for the initialization and optimization algorithms used in <code>gls</code> . Defaults to <code>list(singular.ok = FALSE)</code> , implying that linear dependencies are not allowed in the model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a `glsStruct` object similar to `object`, but with initialized model components.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [Initialize.corStruct](#), [Initialize.varFunc](#), [Initialize](#)

---

```
Initialize.lmeStruct
```

*Initialize an lmeStruct Object*

---

**Description**

The individual linear mixed-effects model components of the `lmeStruct` list are initialized.

**Usage**

```
## S3 method for class 'lmeStruct'
Initialize(object, data, groups, conLin, control, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">lmeStruct</a> ", representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>groups</code>	a data frame with the grouping factors corresponding to the lme model associated with <code>object</code> as columns, sorted from innermost to outermost grouping level.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix (X) combined with a response vector (y), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying lme model. Defaults to <code>attr(object, "conLin")</code> .
<code>control</code>	an optional list with control parameters for the initialization and optimization algorithms used in lme. Defaults to <code>list(niterEM=20, gradHess=TRUE)</code> , implying that 20 EM iterations are to be used in the derivation of initial estimates for the coefficients of the <code>reStruct</code> component of <code>object</code> and, if possible, numerical gradient vectors and Hessian matrices for the log-likelihood function are to be used in the optimization algorithm.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an `lmeStruct` object similar to `object`, but with initialized model components.

**Author(s)**

José Pinheiro and Douglas Bates <[bates@stat.wisc.edu](mailto:bates@stat.wisc.edu)>

**See Also**

---

Initialize.reStruct

Initialize reStruct Object

---

## Description

Initial estimates for the parameters in the `pdMat` objects forming `object`, which have not yet been initialized, are obtained using the methodology described in Bates and Pinheiro (1998). These estimates may be refined using a series of EM iterations, as described in Bates and Pinheiro (1998). The number of EM iterations to be used is defined in `control`.

## Usage

```
## S3 method for class 'reStruct'
Initialize(object, data, conLin, control, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>conLin</code>	a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model.
<code>control</code>	an optional list with a single component <code>niterEM</code> controlling the number of iterations for the EM algorithm used to refine initial parameter estimates. It is given as a list for compatibility with other <code>Initialize</code> methods. Defaults to <code>list(niterEM = 20)</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

an `reStruct` object similar to `object`, but with all `pdMat` components initialized.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[reStruct](#), [pdMat](#), [Initialize](#)

---

`Initialize.varFunc` *Initialize varFunc Object*

---

## Description

This method initializes `object` by evaluating its associated covariate(s) and grouping factor, if any is present, in `data`; determining if the covariate(s) need to be updated when the values of the coefficients associated with `object` change; initializing the log-likelihood and the weights associated with `object`; and assigning initial values for the coefficients in `object`, if none were present. The covariate(s) will only be initialized if no update is needed when `coef(object)` changes.

## Usage

```
## S3 method for class 'varFunc'
Initialize(object, data, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>varFunc</code> ", representing a variance function structure.
<code>data</code>	a data frame in which to evaluate the variables named in <code>formula(object)</code> .
<code>...</code>	this argument is included to make this method compatible with the generic.

## Value

an initialized object with the same class as `object` representing a variance function structure.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[Initialize](#)

## Examples

```
vfl <- varPower( form = ~ age | Sex )
vfl <- Initialize( vfl, Orthodont )
```

---

intervals*Confidence Intervals on Coefficients*

---

**Description**

Confidence intervals on the parameters associated with the model represented by `object` are obtained. This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `gls`, `lme`, and `lmList`.

**Usage**

```
intervals(object, level, ...)
```

**Arguments**

<code>object</code>	a fitted model object from which parameter estimates can be extracted.
<code>level</code>	an optional numeric value for the interval confidence level. Defaults to 0.95.
<code>...</code>	some methods for the generic may require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

intervals.gls

*Confidence Intervals on gls Parameters***Description**

Approximate confidence intervals for the parameters in the linear model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale.

**Usage**

```
## S3 method for class 'gls'
intervals(object, level, which, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>gls</code> ", representing a generalized least squares fitted linear model.
<code>level</code>	an optional numeric value for the interval confidence level. Defaults to 0.95.
<code>which</code>	an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are " <code>all</code> " for all parameters, " <code>var-cov</code> " for the variance-covariance parameters only, and " <code>coef</code> " for the linear model coefficients only. Defaults to " <code>all</code> ".
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by data frames with rows corresponding to parameters and columns `lower`, `est`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

<code>coef</code>	linear model coefficients, only present when <code>which</code> is not equal to " <code>var-cov</code> ".
<code>corStruct</code>	correlation parameters, only present when <code>which</code> is not equal to " <code>coef</code> " and a correlation structure is used in <code>object</code> .
<code>varFunc</code>	variance function parameters, only present when <code>which</code> is not equal to " <code>coef</code> " and a variance function structure is used in <code>object</code> .
<code>sigma</code>	residual standard error.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

<code>intervals.lme</code>	<i>Confidence Intervals on lme Parameters</i>
----------------------------	---

---

Description

Approximate confidence intervals for the parameters in the linear mixed-effects model represented by `object` are obtained, using a normal approximation to the distribution of the (restricted) maximum likelihood estimators (the estimators are assumed to have a normal distribution centered at the true parameter values and with covariance matrix equal to the negative inverse Hessian matrix of the (restricted) log-likelihood evaluated at the estimated parameters). Confidence intervals are obtained in an unconstrained scale first, using the normal approximation, and, if necessary, transformed to the constrained scale. The `pdNatural` parametrization is used for general positive-definite matrices.

Usage

```
## S3 method for class 'lme'
intervals(object, level, which, ...)
```

Arguments

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
<code>level</code>	an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
<code>which</code>	an optional character string specifying the subset of parameters for which to construct the confidence intervals. Possible values are " <code>all</code> " for all parameters, " <code>var-cov</code> " for the variance-covariance parameters only, and " <code>fixed</code> " for the fixed effects only. Defaults to " <code>all</code> ".
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

Value

a list with components given by data frames with rows corresponding to parameters and columns `lower`, `est.`, and `upper` representing respectively lower confidence limits, the estimated values, and upper confidence limits for the parameters. Possible components are:

<code>fixed</code>	fixed effects, only present when <code>which</code> is not equal to " <code>var-cov</code> ".
<code>reStruct</code>	random effects variance-covariance parameters, only present when <code>which</code> is not equal to " <code>fixed</code> ".

<code>corStruct</code>	within-group correlation parameters, only present when <code>which</code> is not equal to <code>"fixed"</code> and a correlation structure is used in <code>object</code> .
<code>varFunc</code>	within-group variance function parameters, only present when <code>which</code> is not equal to <code>"fixed"</code> and a variance function structure is used in <code>object</code> .
<code>sigma</code>	within-group standard deviation.

---

`intervals.lmList`      *Confidence Intervals on lmList Coefficients*

---

**Description**

Confidence intervals on the linear model coefficients are obtained for each `lm` component of `object` and organized into a three dimensional array. The first dimension corresponding to the names of the `object` components. The second dimension is given by `lower`, `est.`, and `upper` corresponding, respectively, to the lower confidence limit, estimated coefficient, and upper confidence limit. The third dimension is given by the coefficients names.

**Usage**

```
## S3 method for class 'lmList'
intervals(object, level, pool, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.
<code>level</code>	an optional numeric value with the confidence level for the intervals. Defaults to 0.95.
<code>pool</code>	an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a three dimensional array with the confidence intervals and estimates for the coefficients of each `lm` component of `object`.

**Examples**

```
fm1 <- lmList(distance ~ age | Subject, Orthodont)
intervals(fm1)
```

---

isBalanced

---

*Check a Design for Balance*

---

**Description**

Check the design of the experiment or study for balance.

**Usage**

```
isBalanced(object, countOnly, level)
```

**Arguments**

<code>object</code>	A <code>groupedData</code> object containing a data frame and a formula that describes the roles of variables in the data frame. The object will have one or more nested grouping factors and a primary covariate.
<code>countOnly</code>	A logical value indicating if the check for balance should only consider the number of observations at each level of the grouping factor(s). Defaults to <code>FALSE</code> .
<code>level</code>	an optional integer vector specifying the desired prediction levels. Levels increase from outermost to innermost grouping, with level 0 representing the population (fixed effects) predictions. Defaults to the innermost level.

**Details**

A design is balanced with respect to the grouping factor(s) if there are the same number of observations at each distinct value of the grouping factor or each combination of distinct levels of the nested grouping factors. If `countOnly` is `FALSE` the design is also checked for balance with respect to the primary covariate, which is often the time of the observation. A design is balanced with respect to the grouping factor and the covariate if the number of observations at each distinct level (or combination of levels for nested factors) is constant and the times at which the observations are taken (in general, the values of the primary covariates) also are constant.

**Value**

TRUE or FALSE according to whether the data are balanced or not

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[table](#), [groupedData](#)

**Examples**

```
isBalanced(Orthodont)           # should return TRUE
isBalanced(Orthodont, countOnly = TRUE) # should return TRUE
isBalanced(Pixel)               # should return FALSE
isBalanced(Pixel, level = 1)    # should return FALSE
```

---

isInitialized	<i>Check if Object is Initialized</i>
---------------	---------------------------------------

---

**Description**

Checks if `object` has been initialized (generally through a call to `Initialize`), by searching for components and attributes which are modified during initialization.

**Usage**

```
isInitialized(object)
```

**Arguments**

`object` any object requiring initialization.

**Value**

a logical value indicating whether `object` has been initialized.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

[Initialize](#)

**Examples**

```
pd1 <- pdDiag(~age)
isInitialized(pd1)
```

LDEsysMat

*Generate system matrix for LDEs***Description**

Generate the system matrix for the linear differential equations determined by a compartment model.

**Usage**

```
LDEsysMat(pars, incidence)
```

**Arguments**

<code>pars</code>	a numeric vector of parameter values.
<code>incidence</code>	an integer matrix with columns named <code>From</code> , <code>To</code> , and <code>Par</code> . Values in the <code>Par</code> column must be in the range 1 to <code>length(pars)</code> . Values in the <code>From</code> column must be between 1 and the number of compartments. Values in the <code>To</code> column must be between 0 and the number of compartments.

**Details**

A compartment model describes material transfer between  $k$  in a system of  $k$  compartments to a linear system of differential equations. Given a description of the system and a vector of parameter values this function returns the system matrix.

This function is intended for use in a general system for solving compartment models, as described in Bates and Watts (1988).

**Value**

A  $k$  by  $k$  numeric matrix.

**Author(s)**

Douglas Bates <bates@stat.wisc.edu>

**References**

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

**Examples**

```
# incidence matrix for a two compartment open system
incidence <-
  matrix(c(1,1,2,2,2,1,3,2,0), ncol = 3, byrow = TRUE,
        dimnames = list(NULL, c("Par", "From", "To")))
incidence
LDEsysMat(c(1.2, 0.3, 0.4), incidence)
```

lme

*Linear Mixed-Effects Models***Description**

This generic function fits a linear mixed-effects model in the formulation described in Laird and Ware (1982) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

The methods `lme.lmList` and `lme.groupedData` are documented separately.

**Usage**

```
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts = NULL, keep.data = TRUE)
```

```
## S3 method for class 'lme'
update(object, fixed., ..., evaluate = TRUE)
```

**Arguments**

- |        |   |
|--------|---|
| object | an object inheriting from class <code>lme</code> , representing a fitted linear mixed-effects model.  |
| fixed  | a two-sided linear formula object describing the fixed-effects part of the model, with the response on the left of a <code>~</code> operator and the terms, separated by <code>+</code> operators, on the right, an <code>"lmList"</code> object, or a <code>"groupedData"</code> object. There is limited support for formulae such as <code>resp ~ 1</code> and <code>resp ~ 0</code> , and less prior to version '3.1-112'.  |
| fixed. | Changes to the fixed-effects formula – see <code>update.formula</code> for details.   |
| data   | an optional data frame containing the variables named in <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , and <code>subset</code> . By default the variables are taken from the environment from which <code>lme</code> is called.  |
| random | optionally, any of the following: (i) a one-sided formula of the form <code>~ x1 + ... + xn   g1/.../gm</code> , with <code>x1 + ... + xn</code> specifying the model for the random effects and <code>g1/.../gm</code> the grouping structure ( <code>m</code> may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form <code>~ x1 + ... + xn   g</code> , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form <code>~ x1 + ... + xn</code> , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>"groupedData"</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> . |

<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If "REML" the model is fit by maximizing the restricted log-likelihood. If "ML" the log-likelihood is maximized. Defaults to "REML".
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>keep.data</code>	logical: should the <code>data</code> argument (if supplied and a data frame) be saved as part of the model object?
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.
<code>evaluate</code>	If <code>TRUE</code> evaluate the new call else return the call.

### Value

An object of class "lme" representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

### Note

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

### Author(s)

fm2 <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
summary(fml)
summary(fm2)
```

---

lme.groupedData	<i>LME fit from groupedData Object</i>
-----------------	--

---

### Description

The response variable and primary covariate in `formula(fixed)` are used to construct the fixed effects model formula. This formula and the `groupedData` object are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

### Usage

```
## S3 method for class 'groupedData'
lme(fixed, data, random, correlation, weights,
    subset, method, na.action, control, contrasts, keep.data = TRUE)
```

**Arguments**

<code>fixed</code>	a data frame inheriting from class <code>"groupedData"</code> .
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>random</code>	optionally, any of the following: (i) a one-sided formula of the form $\sim x_1 + \dots + x_n \mid g_1 / \dots / g_m$ , with $x_1 + \dots + x_n$ specifying the model for the random effects and $g_1 / \dots / g_m$ the grouping structure ( $m$ may be equal to 1, in which case no $/$ is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form $\sim x_1 + \dots + x_n \mid g$ , with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form $\sim x_1 + \dots + x_n$ , or a <code>pdMat</code> object with a formula (i.e. a non-NULL value for <code>formula(object)</code> ), or a list of such formulas or <code>pdMat</code> objects. In this case, the grouping structure formula will be derived from the data used to fit the linear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the order of the elements in the list; (v) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of the available <code>pdMat</code> classes. Defaults to a formula consisting of the right hand side of <code>fixed</code> .
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"REML"</code> .
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>keep.data</code>	logical: should the <code>data</code> argument (if supplied and a data frame) be saved as part of the model object?

**Value**

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject`

for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

lme.lmList	<i>LME fit from lmList Object</i>
------------	-----------------------------------

---

## Description

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `lme.formula`, together with any other additional arguments in the function call. See the documentation on `lme.formula` for a description of that function.

## Usage

```
## S3 method for class 'lmList'
lme(fixed, data, random, correlation, weights, subset, method,
    na.action, control, contrasts, keep.data)
```

## Arguments

<code>fixed</code>	an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> fits with a common model.
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>random</code>	an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"REML"</code> .
<code>na.action</code>	a function that indicates what should happen when the data contain <code>NA</code> s. The default action ( <code>na.fail</code> ) causes <code>lme</code> to print an error message and terminate if there are any incomplete observations.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>lmeControl</code> . Defaults to an empty list.

<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>keep.data</code>	logical: should the <code>data</code> argument (if supplied and a data frame) be saved as part of the model object?

### Value

an object of class `lme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `lmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

lmeControl *Control Values for lme Fit*

---

**Description**

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `lme` function.

**Usage**

```
lmeControl(maxIter, msMaxIter, tolerance, niterEM, msMaxEval, msTol,
           msVerbose, returnObject, gradHess, apVar,
           .relStep, minAbsParApVar,
           opt = c("nlminb", "optim"), optimMethod,
           natural, ...)
```

**Arguments**

<code>maxIter</code>	maximum number of iterations for the <code>lme</code> optimization algorithm. Default is 50.
<code>msMaxIter</code>	maximum number of iterations for the optimization step inside the <code>lme</code> optimization. Default is 50.
<code>tolerance</code>	tolerance for the convergence criterion in the <code>lme</code> algorithm. Default is $1e-6$ .
<code>niterEM</code>	number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
<code>msMaxEval</code>	maximum number of evaluations of the objective function permitted for <code>nlminb</code> . Default is 200.
<code>msTol</code>	tolerance for the convergence criterion on the first iteration when <code>optim</code> is used. Default is $1e-7$ .
<code>msVerbose</code>	a logical value passed as the <code>trace</code> argument to <code>nlminb</code> or <code>optim</code> . Default is <code>FALSE</code> .
<code>returnObject</code>	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is <code>FALSE</code> .
<code>gradHess</code>	a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the internal optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is <code>TRUE</code> .
<code>apVar</code>	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is <code>TRUE</code> .
<code>.relStep</code>	relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .
<code>opt</code>	the optimizer to be used, either <code>"nlminb"</code> (the default) or <code>"optim"</code> .
<code>optimMethod</code>	character - the optimization method to be used with the <code>optim</code> optimizer. The default is <code>"BFGS"</code> . An alternative is <code>"L-BFGS-B"</code> .

<code>minAbsParApVar</code>	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is 0.05.
<code>natural</code>	a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is <code>TRUE</code> .
<code>...</code>	Further named control arguments to be passed to <code>nlminb</code> (those from <code>abs.tol</code> down) or <code>optim</code> (those except <code>trace</code> and <code>maxit</code> ; <code>reltol</code> is used only from the second iteration).

**Value**

a list with components for each of the possible arguments.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

[lme](#), [nlminb](#), [optim](#)

**Examples**

```
# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
lmeControl(msMaxIter = 20, msVerbose = TRUE)
```

---

<code>lmeObject</code>	<i>Fitted lme Object</i>
------------------------	--------------------------

---

**Description**

An object returned by the `lme` function, inheriting from class `lme` and representing a fitted linear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

**Value**

The following components must be included in a legitimate `lme` object.

<code>apVar</code>	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>lme</code> , this component is equal to <code>NULL</code> .
<code>call</code>	a list containing an image of the <code>lme</code> call that produced the object.
<code>coefficients</code>	a list with two components, <code>fixed</code> and <code>random</code> , where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the <code>random</code> list, the columns refer to the random effects and the rows to the groups.

<code>contrasts</code>	a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the lme model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the lme fit, including the components <code>N</code> - the number of observations in the data, <code>Q</code> - the number of grouping levels, <code>qvec</code> - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), <code>ngrps</code> - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and <code>ncol</code> - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).
<code>fitted</code>	a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
<code>fixDF</code>	a list with components <code>X</code> and <code>terms</code> specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
<code>groups</code>	a data frame with the grouping factors as columns. The grouping level increases from left to right.
<code>logLik</code>	the (restricted) log-likelihood at convergence.
<code>method</code>	the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
<code>modelStruct</code>	an object inheriting from class <code>lmeStruct</code> , representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
<code>numIter</code>	the number of iterations used in the iterative algorithm.
<code>residuals</code>	a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
<code>sigma</code>	the estimated within-group error standard deviation.
<code>varFix</code>	an approximate covariance matrix of the fixed effects estimates.

lmeStruct	<i>Linear Mixed-Effects Structure</i>
-----------	---------------------------------------

---

**Description**

A linear mixed-effects structure is a list of model components representing different sets of parameters in the linear mixed-effects model. An `lmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `lmeStruct` list.

**Usage**

```
lmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

- `reStruct` a `reStruct` representing a random effects structure.
- `corStruct` an optional `corStruct` object, representing a correlation structure. Default is `NULL`.
- `varStruct` an optional `varFunc` object, representing a variance function structure. Default is `NULL`.

**Value**

a list of model components determining the parameters to be estimated for the associated linear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
lms1 <- lmeStruct(reStruct(~age), corAR1(), varPower())
```

---

lmList	<i>List of lm Objects with a Common Model</i>
--------	---

---

**Description**

Data is partitioned according to the levels of the grouping factor `g` and individual `lm` fits are obtained for each data partition, using the model defined in `object`.

**Usage**

```
lmList(object, data, level, subset, na.action, pool)
## S3 method for class 'lmList'
update(object, formula., ..., evaluate = TRUE)
## S3 method for class 'lmList'
print(x, pool, ...)
```

**Arguments**

<code>object</code>	For <code>lmList</code> , either a linear formula object of the form $y \sim x_1 + \dots + x_n \mid g$ or a <code>groupedData</code> object. In the formula object, $y$ represents the response, $x_1, \dots, x_n$ the covariates, and $g$ the grouping factor specifying the partitioning of the data according to which different <code>lm</code> fits should be performed. The grouping factor $g$ may be omitted from the formula, in which case the grouping structure will be obtained from <code>data</code> , which must inherit from class <code>groupedData</code> . The method function <code>lmList.groupedData</code> is documented separately. For the method <code>update.lmList</code> , <code>object</code> is an object inheriting from class <code>lmList</code> .
<code>formula</code>	(used in <code>update.lmList</code> only) a two-sided linear formula with the common model for the individuals <code>lm</code> fits.
<code>formula.</code>	Changes to the formula – see <code>update.formula</code> for details.
<code>data</code>	a data frame in which to interpret the variables named in <code>object</code> .
<code>level</code>	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
<code>subset</code>	an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.
<code>pool</code>	an optional logical value indicating whether a pooled estimate of the residual standard error should be used in calculations of standard deviations or standard errors for summaries.
<code>x</code>	an object inheriting from class <code>lmList</code> to be printed.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.
<code>evaluate</code>	If <code>TRUE</code> evaluate the new call else return the call.

**Value**

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

fml <- lmList(distance ~ age | Subject, Orthodont)
summary(fml)
```

---

`lmList.groupedData` *lmList Fit from a groupedData Object*

---

**Description**

The response variable and primary covariate in `formula(object)` are used to construct the linear model formula. This formula and the `groupedData` object are passed as the `object` and `data` arguments to `lmList.formula`, together with any other additional arguments in the function call. See the documentation on `lmList.formula` for a description of that function.

**Usage**

```
## S3 method for class 'groupedData'
lmList(object, data, level, subset, na.action, pool)
```

**Arguments**

<code>object</code>	a data frame inheriting from class " <code>groupedData</code> ".
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>level</code>	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
<code>subset</code>	an optional expression indicating which subset of the rows of <code>data</code> should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>lmList</code> to print an error message and terminate if there are any incomplete observations.
<code>pool</code>	an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.

**Value**

a list of `lm` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `lmList` object.

logDet

---

*Extract the Logarithm of the Determinant*

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, several `pdMat` classes, and `reStruct`.

**Usage**

```
logDet(object, ...)
```

**Arguments**

<code>object</code>	any object from which a matrix, or list of matrices, can be extracted
<code>...</code>	some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

## see the method function documentation
```

---

`logDet.corStruct`     *Extract corStruct Log-Determinant*

---

### Description

This method function extracts the logarithm of the determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

### Usage

```
## S3 method for class 'corStruct'
logDet(object, covariate, ...)
```

### Arguments

<code>object</code>	an object inheriting from class " <code>corStruct</code> ", representing a correlation structure.
<code>covariate</code>	an optional covariate vector (matrix), or list of covariate vectors (matrices), at which values the correlation matrix, or list of correlation matrices, are to be evaluated. Defaults to <code>getCovariate(object)</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the log-determinant of a square-root factor of the correlation matrix associated with `object`, or the sum of the log-determinants of square-root factors of the list of correlation matrices associated with `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

### Examples

```
cs1 <- corAR1(0.3)
logDet(cs1, covariate = 1:4)
```

---

logDet.pdMat	<i>Extract Log-Determinant from a pdMat Object</i>
--------------	--

---

**Description**

This method function extracts the logarithm of the determinant of a square-root factor of the positive-definite matrix represented by `object`.

**Usage**

```
## S3 method for class 'pdMat'
logDet(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-determinant of a square-root factor of the positive-definite matrix represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[pdMat](#), [logDet](#)

**Examples**

```
pd1 <- pdSymm(diag(1:3))
logDet(pd1)
```

---

logDet.reStruct	<i>Extract reStruct Log-Determinants</i>
-----------------	--

---

**Description**

Calculates, for each of the `pdMat` components of `object`, the logarithm of the determinant of a square-root factor.

**Usage**

```
## S3 method for class 'reStruct'
logDet(object, ...)
```

**Arguments**

`object` an object inheriting from class "`reStruct`", representing a random effects structure and consisting of a list of `pdMat` objects.

`...` some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the log-determinants of square-root factors of the `pdMat` components of `object`.

**Author(s)**

José Pinheiro

**See Also**

`reStruct`, `pdMat`, `logDet`

**Examples**

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ)))
logDet(rs1)
```

---

<code>logLik.corStruct</code>	<i>Extract corStruct Log-Likelihood</i>
-------------------------------	---

---

**Description**

This method function extracts the component of a Gaussian log-likelihood associated with the correlation structure, which is equal to the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the matrix (or matrices) represented by `object`.

**Usage**

```
## S3 method for class 'corStruct'
logLik(object, data, ...)
```

**Arguments**

`object` an object inheriting from class "`corStruct`", representing a correlation structure.

`data` this argument is included to make this method function compatible with other `logLik` methods and will be ignored.

`...` some methods for this generic require additional arguments. None are used in this method.

**Value**

the negative of the logarithm of the determinant (or sum of the logarithms of the determinants) of the correlation matrix (or matrices) represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[logDet.corStruct](#), [logLik.lme](#),

**Examples**

```
cs1 <- corAR1(0.2)
cs1 <- Initialize(cs1, data = Orthodont)
logLik(cs1)
```

---

logLik.glsStruct	<i>Log-Likelihood of a glsStruct Object</i>
------------------	---

---

**Description**

`Pars` is used to update the coefficients of the model components of `object` and the individual (restricted) log-likelihood contributions of each component are added together. The type of log-likelihood (restricted or not) is determined by the `settings` attribute of `object`.

**Usage**

```
## S3 method for class 'glsStruct'
logLik(object, Pars, conLin, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">glsStruct</a> ", representing a list of linear model components, such as <code>corStruct</code> and " <a href="#">varFunc</a> " objects.
<code>Pars</code>	the parameter values at which the (restricted) log-likelihood is to be evaluated.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying linear model. Defaults to <code>attr(object, "conLin")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the (restricted) log-likelihood for the linear model described by `object`, evaluated at `Pars`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gls](#), [glsStruct](#), [logLik.lme](#)

---

logLik.gnls*Log-Likelihood of a gnls Object*

---

**Description**

Returns the log-likelihood value of the nonlinear model represented by `object` evaluated at the estimated coefficients.

**Usage**

```
## S3 method for class 'gnls'
logLik(object, REML, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">gnls</a> ", representing a generalized nonlinear least squares fitted model.
<code>REML</code>	an logical value for consistency with <code>logLik.gls</code> , but only <code>FALSE</code> is accepted..
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood of the linear model represented by `object` evaluated at the estimated coefficients.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gnls](#), [logLik.lme](#)

**Examples**

fm1 <- gnls(weight ~ SSlogis(Time, Asym, xmid, scal), Soybean,
            weights = varPower())
logLik(fm1)
```

---

logLik.gnlsStruct     *Log-Likelihood of a gnlsStruct Object*

---

### Description

`Pars` is used to update the coefficients of the model components of `object` and the individual log-likelihood contributions of each component are added together.

### Usage

```
## S3 method for class 'gnlsStruct'
logLik(object, Pars, conLin, ...)
```

### Arguments

<code>object</code>	an object inheriting from class <code>gnlsStruct</code> , representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable.
<code>Pars</code>	the parameter values at which the log-likelihood is to be evaluated.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying nonlinear model. Defaults to <code>attr(object, "conLin")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the log-likelihood for the linear model described by `object`, evaluated at `Pars`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

logLik.lme     *Log-Likelihood of an lme Object*

---

### Description

If `REML=FALSE`, returns the log-likelihood value of the linear mixed-effects model represented by `object` evaluated at the estimated coefficients; else, the restricted log-likelihood evaluated at the estimated coefficients is returned.

**Usage**

```
## S3 method for class 'lme'
logLik(object, REML, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
<code>REML</code>	an optional logical value. If <code>TRUE</code> the restricted log-likelihood is returned, else, if <code>FALSE</code> , the log-likelihood is returned. Defaults to the method of estimation used, that is <code>TRUE</code> if and only <code>object</code> was fitted with <code>method = "REML"</code> (the default for these fitting functions).
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the (restricted) log-likelihood of the model represented by `object` evaluated at the estimated coefficients.

**Author(s)**

José Pinheiro and Douglas Bates

**See Also**

`lme`, `lmeStruct`, `logLik.lme`

---

logLik.lmList

*Log-Likelihood of an lmList Object*

---

**Description**

If `pool=FALSE`, the (restricted) log-likelihoods of the `lm` components of `object` are summed together. Else, the (restricted) log-likelihood of the `lm` fit with different coefficients for each level of the grouping factor associated with the partitioning of the `object` components is obtained.

**Usage**

```
## S3 method for class 'lmList'
logLik(object, REML, pool, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.
<code>REML</code>	an optional logical value. If <code>TRUE</code> the restricted log-likelihood is returned, else, if <code>FALSE</code> , the log-likelihood is returned. Defaults to <code>FALSE</code> .
<code>pool</code>	an optional logical value indicating whether all <code>lm</code> components of <code>object</code> may be assumed to have the same error variance. Default is <code>attr(object, "pool")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

either the sum of the (restricted) log-likelihoods of each `lm` component in `object`, or the (restricted) log-likelihood for the `lm` fit with separate coefficients for each component of `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

fml <- lmList(distance ~ age | Subject, Orthodont)
logLik(fml)    # returns NA when it should not
```

---

<code>logLik.reStruct</code>	<i>Calculate reStruct Log-Likelihood</i>
------------------------------	--

---

**Description**

Calculates the log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods are described in Bates and Pinheiro (1998).

**Usage**

```
## S3 method for class 'reStruct'
logLik(object, conLin, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>conLin</code>	a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the log-likelihood, or restricted log-likelihood, of linear mixed-effects model represented by `object` and `conLin`, evaluated at `coef{object}`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`, `pdMat`, `logLik.lme`

---

<code>logLik.varFunc</code>	<i>Extract varFunc logLik</i>
-----------------------------	-------------------------------

---

**Description**

This method function extracts the component of a Gaussian log-likelihood associated with the variance function structure represented by `object`, which is equal to the sum of the logarithms of the corresponding weights.

**Usage**

```
## S3 method for class 'varFunc'
logLik(object, data, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>varFunc</code> ", representing a variance function structure.
<code>data</code>	this argument is included to make this method function compatible with other <code>logLik</code> methods and will be ignored.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the sum of the logarithms of the weights corresponding to the variance function structure represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[logLik.lme](#)

**Examples**

```
vf1 <- varPower(form = ~age)
vf1 <- Initialize(vf1, Orthodont)
coef(vf1) <- 0.1
logLik(vf1)
```

Machines

*Productivity Scores for Machines and Workers*

---

**Description**

The `Machines` data frame has 54 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Worker** an ordered factor giving the unique identifier for the worker.

**Machine** a factor with levels A, B, and C identifying the machine brand.

**score** a productivity score.

**Details**

Data on an experiment to compare three brands of machines used in an industrial process are presented in Milliken and Johnson (p. 285, 1992). Six workers were chosen randomly among the employees of a factory to operate each machine three times. The response is an overall productivity score taking into account the number and quality of components produced.

MathAchieve	<i>Mathematics achievement scores</i>
-------------	---------------------------------------

---

### Description

The MathAchieve data frame has 7185 rows and 6 columns.

### Format

This data frame contains the following columns:

**School** an ordered factor identifying the school that the student attends

**Minority** a factor with levels No Yes indicating if the student is a member of a minority racial group.

**Sex** a factor with levels Male Female

**SES** a numeric vector of socio-economic status.

**MathAch** a numeric vector of mathematics achievement scores.

**MEANSES** a numeric vector of the mean SES for the school.

### Details

Each row in this data frame contains the data for one student.

### Examples

```
summary(MathAchieve)
```

---

MathAchSchool	<i>School demographic data for MathAchieve</i>
---------------	--

---

### Description

The MathAchSchool data frame has 160 rows and 7 columns.

### Format

This data frame contains the following columns:

**School** a factor giving the school on which the measurement is made.

**Size** a numeric vector giving the number of students in the school

**Sector** a factor with levels Public Catholic

**PRACAD** a numeric vector giving the percentage of students on the academic track

**DISCLIM** a numeric vector measuring the discrimination climate

**HIMINTY** a factor with levels 0 1

**MEANSES** a numeric vector giving the mean SES score.

### Details

These variables give the school-level demographic data to accompany the MathAchieve data.

Matrix

*Assign Matrix Values***Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `pdMat`, `pdBlocked`, and `reStruct`.

**Usage**

```
matrix(object) <- value
```

**Arguments**

<code>object</code>	any object to which <code>as.matrix</code> can be applied.
<code>value</code>	a matrix, or list of matrices, with the same dimensions as <code>as.matrix(object)</code> with the new values to be assigned to the matrix associated with <code>object</code> .

**Value**

will depend on the method function; see the appropriate documentation.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`as.matrix`

**Examples**

```
## see the method function documentation
```

Matrix.pdMat

*Assign Matrix to a pdMat Object***Description**

The positive-definite matrix represented by `object` is replaced by `value`. If the original matrix had row and/or column names, the corresponding names for `value` can either be `NULL`, or a permutation of the original names.

**Usage**

```
## S3 replacement method for class 'pdMat'
matrix(object) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>pdMat</code> ", representing a positive definite matrix.
<code>value</code>	a matrix with the new values to be assigned to the positive-definite matrix represented by <code>object</code> . Must have the same dimensions as <code>as.matrix(object)</code> .

**Value**

a `pdMat` object similar to `object`, but with its coefficients modified to produce the matrix in `value`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`pdMat`, "`matrix<-`"

**Examples**

```
pd1 <- pdSymm(diag(3))
matrix(pd1) <- diag(1:3)
pd1
```

---

`Matrix.reStruct`      *Assign reStruct Matrices*

---

**Description**

The individual matrices in `value` are assigned to each `pdMat` component of `object`, in the order they are listed. The new matrices must have the same dimensions as the matrices they are meant to replace.

**Usage**

```
## S3 replacement method for class 'reStruct'
matrix(object) <- value
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>value</code>	a matrix, or list of matrices, with the new values to be assigned to the matrices associated with the <code>pdMat</code> components of <code>object</code> .

**Value**

an `reStruct` object similar to `object`, but with the coefficients of the individual `pdMat` components modified to produce the matrices listed in `value`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`reStruct`, `pdMat`, "`matrix<-`"

**Examples**

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
matrix(rs1) <- list(diag(2), 3)
```

---

Meat	<i>Tenderness of meat</i>
------	---------------------------

---

**Description**

The `Meat` data frame has 30 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Storage** an ordered factor specifying the storage treatment - 1 (0 days), 2 (1 day), 3 (2 days), 4 (4 days), 5 (9 days), and 6 (18 days)

**score** a numeric vector giving the tenderness score of beef roast.

**Block** an ordered factor identifying the muscle from which the roast was extracted with levels `II < V < I < III < IV`

**Pair** an ordered factor giving the unique identifier for each pair of beef roasts with levels `II-1 < ... < IV-1`

**Details**

Cochran and Cox (section 11.51, 1957) describe data from an experiment conducted at Iowa State College (Paul, 1943) to compare the effects of length of cold storage on the tenderness of beef roasts. Six storage periods ranging from 0 to 18 days were used. Thirty roasts were scored by four judges on a scale from 0 to 10, with the score increasing with tenderness. The response was the sum of all four scores. Left and right roasts from the same animal were grouped into pairs, which were further grouped into five blocks, according to the muscle from which they were extracted. Different storage periods were applied to each roast within a pair according to a balanced incomplete block design.

Milk

*Protein content of cows' milk***Description**

The `Milk` data frame has 1337 rows and 4 columns.

**Format**

This data frame contains the following columns:

**protein** a numeric vector giving the protein content of the milk.

**Time** a numeric vector giving the time since calving (weeks).

**Cow** an ordered factor giving a unique identifier for each cow.

**Diet** a factor with levels `barley`, `barley+lupins`, and `lupins` identifying the diet for each cow.

**Details**

Diggle, Liang, and Zeger (1994) describe data on the protein content of cows' milk in the weeks following calving. The cattle are grouped according to whether they are fed a diet with barley alone, with barley and lupins, or with lupins alone.

Diggle, Peter J., Liang, Kung-Yee and Zeger, Scott L. (1994), *Analysis of longitudinal data*, Oxford University Press, Oxford.

---

`model.matrix.reStruct`
*reStruct Model Matrix*

---

**Description**

The model matrices for each element of `formula(object)`, calculated using `data`, are bound together column-wise. When multiple grouping levels are present (i.e. when `length(object) > 1`), the individual model matrices are combined from innermost (at the leftmost position) to outermost (at the rightmost position).

**Usage**

```
## S3 method for class 'reStruct'
model.matrix(object, data, contrast, ...)
```

Arguments

<code>object</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>data</code>	a data frame in which to evaluate the variables defined in <code>formula(object)</code> .
<code>contrast</code>	an optional named list specifying the contrasts to be used for representing the factor variables in <code>data</code> . The components names should match the names of the variables in <code>data</code> for which the contrasts are to be specified. The components of this list will be used as the <code>contrasts</code> attribute of the corresponding factor. If missing, the default contrast specification is used.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

Value

a matrix obtained by binding together, column-wise, the model matrices for each element of `formula(object)`.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

See Also

`model.matrix`, `contrasts`, `reStruct`, `formula.reStruct`

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
model.matrix(rs1, Pixel)
```

---

Muscle	<i>Contraction of heart muscle sections</i>
--------	---

---

Description

The `Muscle` data frame has 60 rows and 3 columns.

Format

This data frame contains the following columns:

**Strip** an ordered factor indicating the strip of muscle being measured.

**conc** a numeric vector giving the concentration of  $\text{CaCl}_2$

**length** a numeric vector giving the shortening of the heart muscle strip.

Details

Baumann and Waldvogel (1963) describe data on the shortening of heart muscle strips dipped in a  $\text{CaCl}_2$  solution. The muscle strips are taken from the left auricle of a rat's heart.

---

Names	<i>Names Associated with an Object</i>
-------	--

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `formula`, `modelStruct`, `pdBlocked`, `pdMat`, and `reStruct`.

**Usage**

```
Names(object, ...)  
Names(object, ...) <- value
```

**Arguments**

<code>object</code>	any object for which names can be extracted and/or assigned.
<code>...</code>	some methods for this generic function require additional arguments.
<code>value</code>	names to be assigned to <code>object</code> .

**Value**

will depend on the method function used; see the appropriate documentation.

**SIDE EFFECTS**

On the left side of an assignment, sets the names associated with `object` to `value`, which must have an appropriate length.

**Note**

If `names` were generic, there would be no need for this generic function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
## see the method function documentation
```

---

`Names.formula`*Extract Names from a formula*

---

### Description

This method function returns the names of the terms corresponding to the right hand side of `object` (treated as a linear formula), obtained as the column names of the corresponding `model.matrix`.

### Usage

```
## S3 method for class 'formula'
Names(object, data, exclude, ...)
```

### Arguments

<code>object</code>	an object inheriting from class " <code>formula</code> ".
<code>data</code>	an optional data frame containing the variables specified in <code>object</code> . By default the variables are taken from the environment from which <code>Names.formula</code> is called.
<code>exclude</code>	an optional character vector with names to be excluded from the returned value. Default is <code>c("pi", ".")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a character vector with the column names of the `model.matrix` corresponding to the right hand side of `object` which are not listed in `excluded`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`model.matrix`, `terms`, `Names`

### Examples

```
Names(distance ~ Sex * age, data = Orthodont)
```

---

Names.pdBlocked	<i>Names of a pdBlocked Object</i>
-----------------	------------------------------------

---

## Description

This method function extracts the first element of the `Dimnames` attribute, which contains the column names, for each block diagonal element in the matrix represented by `object`.

## Usage

```
## S3 method for class 'pdBlocked'  
Names(object, asList, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <a href="#">pdBlocked</a> " representing a positive-definite matrix with block diagonal structure
<code>asList</code>	a logical value. If <code>TRUE</code> a list with the names for each block diagonal element is returned. If <code>FALSE</code> a character vector with all column names is returned. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

if `asList` is `FALSE`, a character vector with column names of the matrix represented by `object`; otherwise, if `asList` is `TRUE`, a list with components given by the column names of the individual block diagonal elements in the matrix represented by `object`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[Names](#), [Names.pdMat](#)

## Examples

```
pd1 <- pdBlocked(list(~Sex ~ 1, ~age ~ 1), data = Orthodont)  
Names(pd1)
```

---

Names.pdMat*Names of a pdMat Object*

---

## Description

This method function returns the first element of the `Dimnames` attribute of `object`, which contains the column names of the matrix represented by `object`.

## Usage

```
## S3 method for class 'pdMat'
Names(object, ...)
## S3 replacement method for class 'pdMat'
Names(object, ...) <- value
```

## Arguments

<code>object</code>	an object inheriting from class " <code>pdMat</code> ", representing a positive-definite matrix.
<code>value</code>	a character vector with the replacement values for the column and row names of the matrix represented by <code>object</code> . It must have length equal to the dimension of the matrix represented by <code>object</code> and, if names have been previously assigned to <code>object</code> , it must correspond to a permutation of the original names.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

if `object` has a `Dimnames` attribute then the first element of this attribute is returned; otherwise `NULL`.

## SIDE EFFECTS

On the left side of an assignment, sets the `Dimnames` attribute of `object` to `list(value, value)`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[Names](#), [Names.pdBlocked](#)

## Examples

```
pd1 <- pdSymm(~age, data = Orthodont)
Names(pd1)
```

---

Names.reStruct	<i>Names of an reStruct Object</i>
----------------	------------------------------------

---

## Description

This method function extracts the column names of each of the positive-definite matrices represented the `pdMat` elements of `object`.

## Usage

```
## S3 method for class 'reStruct'
Names(object, ...)
## S3 replacement method for class 'reStruct'
Names(object, ...) <- value
```

## Arguments

<code>object</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>value</code>	a list of character vectors with the replacement values for the names of the individual <code>pdMat</code> objects that form <code>object</code> . It must have the same length as <code>object</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

a list containing the column names of each of the positive-definite matrices represented by the `pdMat` elements of `object`.

## SIDE EFFECTS

On the left side of an assignment, sets the `Names` of the `pdMat` elements of `object` to the corresponding element of `value`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

`reStruct`, `pdMat`, `Names.pdMat`

## Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
Names(rs1)
```

---

needUpdate	<i>Check if Update is Needed</i>
------------	----------------------------------

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. By default, it tries to extract a `needUpdate` attribute of `object`. If this is `NULL` or `FALSE` it returns `FALSE`; else it returns `TRUE`. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

### Usage

```
needUpdate(object)
```

### Arguments

`object`            any object

### Value

a logical value indicating whether `object` needs to be updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[needUpdate.modelStruct](#)

### Examples

```
vf1 <- varExp()
vf1 <- Initialize(vf1, data = Orthodont)
needUpdate(vf1)
```

---

needUpdate.modelStruct	<i>Check if a modelStruct Object Needs Updating</i>
------------------------	---

---

### Description

This method function checks if any of the elements of `object` needs to be updated. Updating of objects usually takes place in iterative algorithms in which auxiliary quantities associated with the object, and not being optimized over, may change.

### Usage

```
## S3 method for class 'modelStruct'
needUpdate(object)
```

**Arguments**

`object` an object inheriting from class "modelStruct", representing a list of model components, such as `corStruct` and `varFunc` objects.

**Value**

a logical value indicating whether any element of `object` needs to be updated.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[needUpdate](#)

**Examples**

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),  
  varStruct = varPower(form = ~age))  
needUpdate(lms1)
```

---

Nitrendipene

*Assay of nitrendipene*

---

**Description**

The Nitrendipene data frame has 89 rows and 4 columns.

**Format**

This data frame contains the following columns:

**activity** a numeric vector

**NIF** a numeric vector

**Tissue** an ordered factor with levels 2 < 1 < 3 < 4

**log.NIF** a numeric vector

**Source**

Bates, D. M. and Watts, D. G. (1988), *Nonlinear Regression Analysis and Its Applications*, Wiley, New York.

nlme

*Nonlinear Mixed-Effects Models***Description**

This generic function fits a nonlinear mixed-effects model in the formulation described in Lindstrom and Bates (1990) but allowing for nested random effects. The within-group errors are allowed to be correlated and/or have unequal variances.

**Usage**

```
nlme(model, data, fixed, random, groups, start, correlation, weights,
      subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

- |        |  |
|--------|--|
| model  | a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters and covariates on the right, or an <code>nlsList</code> object. If <code>data</code> is given, all names used in the formula should be defined as parameters or variables in the data frame. The method function <code>nlme.nlsList</code> is documented separately.  |
| data   | an optional data frame containing the variables named in <code>model</code> , <code>fixed</code> , <code>random</code> , <code>correlation</code> , <code>weights</code> , <code>subset</code> , and <code>naPattern</code> . By default the variables are taken from the environment from which <code>nlme</code> is called.  |
| fixed  | a two-sided linear formula of the form <code>f1+...+fn~x1+...+xm</code> , or a list of two-sided formulas of the form <code>f1~x1+...+xm</code> , with possibly different models for different parameters. The <code>f1, ..., fn</code> are the names of parameters included on the right hand side of <code>model</code> and the <code>x1+...+xm</code> expressions define linear models for these parameters (when the left hand side of the formula contains several parameters, they all are assumed to follow the same linear model, described by the right hand side expression). A <code>1</code> on the right hand side of the formula(s) indicates a single fixed effects for the corresponding parameter(s).   |
| random | optionally, any of the following: (i) a two-sided formula of the form <code>r1+...+rn~x1+...+xm   g1/.../gQ</code> , with <code>r1, ..., rn</code> naming parameters included on the right hand side of <code>model</code> , <code>x1+...+xm</code> specifying the random-effects model for these parameters and <code>g1/.../gQ</code> the grouping structure ( <code>Q</code> may be equal to 1, in which case no <code>/</code> is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a two-sided formula of the form <code>r1+...+rn~x1+...+xm</code> , a list of two-sided formulas of the form <code>r1~x1+...+xm</code> , with possibly different random-effects models for different parameters, a <code>pdMat</code> object with a two-sided formula, or list of two-sided formulas (i.e. a non-NULL value for <code>formula(random)</code> ), or a list of <code>pdMat</code> objects with two-sided formulas, or lists of two-sided formulas. In this case, the grouping structure formula will be given in <code>groups</code> , or derived from the data used to fit the nonlinear mixed-effects model, which should inherit from class <code>groupedData</code> ; (iii) a named list of formulas, lists of formulas, or <code>pdMat</code> objects as in (ii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (iv) an <code>reStruct</code> object. See the documentation on <code>pdClasses</code> for a description of |

	the available <code>pdMat</code> classes. Defaults to <code>fixed</code> , resulting in all fixed effects having also random effects.
<code>groups</code>	an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/. . ./gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, . . . , gQ</code> must evaluate to factors in data. The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).
<code>start</code>	an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional <code>random</code> component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.
<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"ML"</code> .
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .

## Value

an object of class `nlme` representing the nonlinear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

**Note**

The function does not do any scaling internally: the optimization will work best when the response is scaled so its variance is of the order of one.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

The model formulation and computational methods are described in Lindstrom, M.J. and Bates, D.M. (1990). The variance-covariance parametrizations are described in Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

```
fm1 <- nlme(height ~ SSasym(age, Asym, R0, lrc),
            data = Loblolly,
            fixed = Asym + R0 + lrc ~ 1,
            random = Asym ~ 1,
            start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
summary(fm1)
fm2 <- update(fm1, random = pdDiag(Asym + lrc ~ 1))
summary(fm2)
```

nlme.nlsList

*NLME fit from nlsList Object***Description**

If the random effects names defined in `random` are a subset of the `lmList` object coefficient names, initial estimates for the covariance matrix of the random effects are obtained (overwriting any values given in `random`). `formula(fixed)` and the `data` argument in the calling sequence used to obtain `fixed` are passed as the `fixed` and `data` arguments to `nlme.formula`, together with any other additional arguments in the function call. See the documentation on `nlme.formula` for a description of that function.

**Usage**

```
## S3 method for class 'nlsList'
nlme(model, data, fixed, random, groups, start, correlation, weights,
      subset, method, na.action, naPattern, control, verbose)
```

**Arguments**

<code>model</code>	an object inheriting from class " <code>nlsList</code> ", representing a list of <code>nls</code> fits with a common model.
<code>data</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>fixed</code>	this argument is included for consistency with the generic function. It is ignored in this method function.
<code>random</code>	an optional one-sided linear formula with no conditioning expression, or a <code>pdMat</code> object with a <code>formula</code> attribute. Multiple levels of grouping are not allowed with this method function. Defaults to a formula consisting of the right hand side of <code>formula(fixed)</code> .
<code>groups</code>	an optional one-sided formula of the form <code>~g1</code> (single level of nesting) or <code>~g1/.../gQ</code> (multiple levels of nesting), specifying the partitions of the data over which the random effects vary. <code>g1, ..., gQ</code> must evaluate to factors in <code>data</code> . The order of nesting, when multiple levels are present, is taken from left to right (i.e. <code>g1</code> is the first level, <code>g2</code> the second, etc.).
<code>start</code>	an optional numeric vector, or list of initial estimates for the fixed effects and random effects. If declared as a numeric vector, it is converted internally to a list with a single component <code>fixed</code> , given by the vector. The <code>fixed</code> component is required, unless the model function inherits from class <code>selfStart</code> , in which case initial values will be derived from a call to <code>nlsList</code> . An optional <code>random</code> component is used to specify initial values for the random effects and should consist of a matrix, or a list of matrices with length equal to the number of grouping levels. Each matrix should have as many rows as the number of groups at the corresponding level and as many columns as the number of random effects in that level.
<code>correlation</code>	an optional <code>corStruct</code> object describing the within-group correlation structure. See the documentation of <code>corClasses</code> for a description of the available <code>corStruct</code> classes. Defaults to <code>NULL</code> , corresponding to no within-group correlations.

<code>weights</code>	an optional <code>varFunc</code> object or one-sided formula describing the within-group heteroscedasticity structure. If given as a formula, it is used as the argument to <code>varFixed</code> , corresponding to fixed variance weights. See the documentation on <code>varClasses</code> for a description of the available <code>varFunc</code> classes. Defaults to <code>NULL</code> , corresponding to homoscedastic within-group errors.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>method</code>	a character string. If <code>"REML"</code> the model is fit by maximizing the restricted log-likelihood. If <code>"ML"</code> the log-likelihood is maximized. Defaults to <code>"ML"</code> .
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlme</code> to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.
<code>control</code>	a list of control values for the estimation algorithm to replace the default values returned by the function <code>nlmeControl</code> . Defaults to an empty list.
<code>verbose</code>	an optional logical value. If <code>TRUE</code> information on the evolution of the iterative algorithm is printed. Default is <code>FALSE</code> .

### Value

an object of class `nlme` representing the linear mixed-effects model fit. Generic functions such as `print`, `plot` and `summary` have methods to show the results of the fit. See `nlmeObject` for the components of the fit. The functions `resid`, `coef`, `fitted`, `fixed.effects`, and `random.effects` can be used to extract some of its components.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

- The computational methods follow on the general framework of Lindstrom, M.J. and Bates, D.M. (1988). The model formulation is described in Laird, N.M. and Ware, J.H. (1982). The variance-covariance parametrizations are described in <Pinheiro, J.C. and Bates., D.M. (1996). The different correlation structures available for the `correlation` argument are described in Box, G.E.P., Jenkins, G.M., and Reinsel G.C. (1994), Littell, R.C., Milliken, G.A., Stroup, W.W., and Wolfinger, R.D. (1996), and Venables, W.N. and Ripley, B.D. (2002). The use of variance functions for linear and nonlinear mixed effects models is presented in detail in Davidian, M. and Giltinan, D.M. (1995).

nlmeControl

*Control Values for nlme Fit*

---

## Description

The values supplied in the function call replace the defaults and a list with all possible arguments is returned. The returned list is used as the `control` argument to the `nlme` function.

## Usage

```
nlmeControl(maxIter, pnlsMaxIter, msMaxIter, minScale,
            tolerance, niterEM, pnlsTol, msTol,
            returnObject, msVerbose, gradHess, apVar, .relStep,
            minAbsParApVar = 0.05,
            opt = c("nlminb", "nlm"), natural = TRUE, ...)
```

## Arguments

<code>maxIter</code>	maximum number of iterations for the <code>nlme</code> optimization algorithm. Default is 50.
<code>pnlsMaxIter</code>	maximum number of iterations for the PNLS optimization step inside the <code>nlme</code> optimization. Default is 7.
<code>msMaxIter</code>	maximum number of iterations for the <code>nlm</code> optimization step inside the <code>nlme</code> optimization. Default is 50.
<code>minScale</code>	minimum factor by which to shrink the default step size in an attempt to decrease the sum of squares in the PNLS step. Default 0.001.
<code>tolerance</code>	tolerance for the convergence criterion in the <code>nlme</code> algorithm. Default is 1e-6.
<code>niterEM</code>	number of iterations for the EM algorithm used to refine the initial estimates of the random effects variance-covariance coefficients. Default is 25.
<code>pnlsTol</code>	tolerance for the convergence criterion in PNLS step. Default is 1e-3.

<code>msTol</code>	tolerance for the convergence criterion in <code>nlm</code> , passed as the <code>gradtol</code> argument to the function (see documentation on <code>nlm</code> ). Default is $1e-7$ .
<code>returnObject</code>	a logical value indicating whether the fitted object should be returned when the maximum number of iterations is reached without convergence of the algorithm. Default is <code>FALSE</code> .
<code>msVerbose</code>	a logical value passed as the <code>trace</code> argument to <code>nlm</code> (see documentation on that function). Default is <code>FALSE</code> .
<code>gradHess</code>	a logical value indicating whether numerical gradient vectors and Hessian matrices of the log-likelihood function should be used in the <code>nlm</code> optimization. This option is only available when the correlation structure ( <code>corStruct</code> ) and the variance function structure ( <code>varFunc</code> ) have no "varying" parameters and the <code>pdMat</code> classes used in the random effects structure are <code>pdSymm</code> (general positive-definite), <code>pdDiag</code> (diagonal), <code>pdIdent</code> (multiple of the identity), or <code>pdCompSymm</code> (compound symmetry). Default is <code>TRUE</code> .
<code>apVar</code>	a logical value indicating whether the approximate covariance matrix of the variance-covariance parameters should be calculated. Default is <code>TRUE</code> .
<code>.relStep</code>	relative step for numerical derivatives calculations. Default is <code>.Machine\$double.eps^(1/3)</code> .
<code>minAbsParApVar</code>	numeric value - minimum absolute parameter value in the approximate variance calculation. The default is <code>0.05</code> .
<code>opt</code>	the optimizer to be used, either <code>"nlminb"</code> (the default) or <code>"nlm"</code> .
<code>natural</code>	a logical value indicating whether the <code>pdNatural</code> parametrization should be used for general positive-definite matrices ( <code>pdSymm</code> ) in <code>reStruct</code> , when the approximate covariance matrix of the estimators is calculated. Default is <code>TRUE</code> .
<code>...</code>	Further named control arguments to be passed to <code>nlminb</code> , where used ( <code>eval.max</code> and those from <code>abs.tol</code> down).

### Value

a list with components for each of the possible arguments.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`nlme`, `nlm`, `optim`, `nlmeStruct`

### Examples

```
# decrease the maximum number iterations in the ms call and
# request that information on the evolution of the ms iterations be printed
nlmeControl(msMaxIter = 20, msVerbose = TRUE)
```

---

nlmeObject	<i>Fitted nlme Object</i>
------------	---------------------------

---

### Description

An object returned by the `nlme` function, inheriting from class "nlme", also inheriting from class "lme", and representing a fitted nonlinear mixed-effects model. Objects of this class have methods for the generic functions `anova`, `coef`, `fitted`, `fixed.effects`, `formula`, `getGroups`, `getResponse`, `intervals`, `logLik`, `pairs`, `plot`, `predict`, `print`, `random.effects`, `residuals`, `summary`, and `update`.

### Value

The following components must be included in a legitimate "nlme" object.

<code>apVar</code>	an approximate covariance matrix for the variance-covariance coefficients. If <code>apVar = FALSE</code> in the list of control values used in the call to <code>nlme</code> , this component is equal to <code>NULL</code> .
<code>call</code>	a list containing an image of the <code>nlme</code> call that produced the object.
<code>coefficients</code>	a list with two components, <code>fixed</code> and <code>random</code> , where the first is a vector containing the estimated fixed effects and the second is a list of matrices with the estimated random effects for each level of grouping. For each matrix in the <code>random</code> list, the columns refer to the random effects and the rows to the groups.
<code>contrasts</code>	a list with the contrasts used to represent factors in the fixed effects formula and/or random effects formula. This information is important for making predictions from a new data frame in which not all levels of the original factors are observed. If no factors are used in the <code>nlme</code> model, this component will be an empty list.
<code>dims</code>	a list with basic dimensions used in the <code>nlme</code> fit, including the components <code>N</code> - the number of observations in the data, <code>Q</code> - the number of grouping levels, <code>qvec</code> - the number of random effects at each level from innermost to outermost (last two values are equal to zero and correspond to the fixed effects and the response), <code>ngrps</code> - the number of groups at each level from innermost to outermost (last two values are one and correspond to the fixed effects and the response), and <code>ncol</code> - the number of columns in the model matrix for each level of grouping from innermost to outermost (last two values are equal to the number of fixed effects and one).
<code>fitted</code>	a data frame with the fitted values as columns. The leftmost column corresponds to the population fixed effects (corresponding to the fixed effects only) and successive columns from left to right correspond to increasing levels of grouping.
<code>fixDF</code>	a list with components <code>X</code> and <code>terms</code> specifying the denominator degrees of freedom for, respectively, t-tests for the individual fixed effects and F-tests for the fixed-effects terms in the models.
<code>groups</code>	a data frame with the grouping factors as columns. The grouping level increases from left to right.
<code>logLik</code>	the (restricted) log-likelihood at convergence.
<code>map</code>	a list with components <code>fmap</code> , <code>rmap</code> , <code>rmapRel</code> , and <code>bmap</code> , specifying various mappings for the fixed and random effects, used to generate predictions from the fitted object.

method	the estimation method: either "ML" for maximum likelihood, or "REML" for restricted maximum likelihood.
modelStruct	an object inheriting from class <code>nlmeStruct</code> , representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
numIter	the number of iterations used in the iterative algorithm.
residuals	a data frame with the residuals as columns. The leftmost column corresponds to the population residuals and successive columns from left to right correspond to increasing levels of grouping.
sigma	the estimated within-group error standard deviation.
varFix	an approximate covariance matrix of the fixed effects estimates.

---

nlmeStruct

*Nonlinear Mixed-Effects Structure*

---

**Description**

A nonlinear mixed-effects structure is a list of model components representing different sets of parameters in the nonlinear mixed-effects model. An `nlmeStruct` list must contain at least a `reStruct` object, but may also contain `corStruct` and `varFunc` objects. `NULL` arguments are not included in the `nlmeStruct` list.

**Usage**

```
nlmeStruct(reStruct, corStruct, varStruct)
```

**Arguments**

reStruct	a <code>reStruct</code> representing a random effects structure.
corStruct	an optional <code>corStruct</code> object, representing a correlation structure. Default is <code>NULL</code> .
varStruct	an optional <code>varFunc</code> object, representing a variance function structure. Default is <code>NULL</code> .

**Value**

a list of model components determining the parameters to be estimated for the associated nonlinear mixed-effects model.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

nlsList

---

*List of nls Objects with a Common Model*

---

**Description**

Data is partitioned according to the levels of the grouping factor defined in `model` and individual `nls` fits are obtained for each data partition, using the model defined in `model`.

**Usage**

```
nlsList(model, data, start, control, level, subset, na.action, pool)
## S3 method for class 'nlsList'
update(object, model., ..., evaluate = TRUE)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>nlsList</code> , representing a list of fitted <code>nls</code> objects.
<code>model</code>	either a nonlinear model formula, with the response on the left of a <code>~</code> operator and an expression involving parameters, covariates, and a grouping factor separated by the <code> </code> operator on the right, or a <code>selfStart</code> function. The method function <code>nlsList.selfStart</code> is documented separately.
<code>model.</code>	Changes to the model – see <code>update.formula</code> for details.
<code>data</code>	a data frame in which to interpret the variables named in <code>model</code> .
<code>start</code>	an optional named list with initial values for the parameters to be estimated in <code>model</code> . It is passed as the <code>start</code> argument to each <code>nls</code> call and is required when the nonlinear function in <code>model</code> does not inherit from class <code>selfStart</code> .
<code>control</code>	a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.
<code>level</code>	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.
<code>pool</code>	an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.

... some methods for this generic require additional arguments. None are used in this method.

evaluate If TRUE evaluate the new call else return the call.

### Value

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

### Examples

```
fm1 <- nlsList(uptake ~ SSasymOff(conc, Asym, lrc, c0),
  data = CO2, start = c(Asym = 30, lrc = -4.5, c0 = 52))
summary(fm1)
```

---

`nlsList.selfStart` *nlsList Fit from a selfStart Function*

---

### Description

The response variable and primary covariate in `formula(data)` are used together with `model` to construct the nonlinear model formula. This is used in the `nls` calls and, because a `selfStarting` model function can calculate initial estimates for its parameters from the data, no starting estimates need to be provided.

### Usage

```
## S3 method for class 'selfStart'
nlsList(model, data, start, control, level, subset, na.action, pool)
```

### Arguments

`model` a "`selfStart`" model function, which calculates initial estimates for the model parameters from `data`.

`data` a data frame in which to interpret the variables in `model`. Because no grouping factor can be specified in `model`, `data` must inherit from class "`groupedData`".

`start` an optional named list with initial values for the parameters to be estimated in `model`. It is passed as the `start` argument to each `nls` call and is required when the nonlinear function in `model` does not inherit from class `selfStart`.

<code>control</code>	a list of control values passed as the <code>control</code> argument to <code>nls</code> . Defaults to an empty list.
<code>level</code>	an optional integer specifying the level of grouping to be used when multiple nested levels of grouping are present.
<code>subset</code>	an optional expression indicating the subset of the rows of <code>data</code> that should be used in the fit. This can be a logical vector, or a numeric vector indicating which observation numbers are to be included, or a character vector of the row names to be included. All observations are included by default.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes <code>nlsList</code> to print an error message and terminate if there are any incomplete observations.
<code>pool</code>	an optional logical value that is preserved as an attribute of the returned value. This will be used as the default for <code>pool</code> in calculations of standard deviations or standard errors for summaries.

### Value

a list of `nls` objects with as many components as the number of groups defined by the grouping factor. A `NULL` value is assigned to the components corresponding to clusters for which the `nls` algorithm failed to converge. Generic functions such as `coef`, `fixed.effects`, `lme`, `pairs`, `plot`, `predict`, `random.effects`, `summary`, and `update` have methods that can be applied to an `nlsList` object.

Oats

*Split-plot Experiment on Varieties of Oats*

---

### Description

The `Oats` data frame has 72 rows and 4 columns.

### Format

This data frame contains the following columns:

**Block** an ordered factor with levels VI < V < III < IV < II < I

**Variety** a factor with levels Golden Rain Marvellous Victory

**nitro** a numeric vector

**yield** a numeric vector

## Details

These data have been introduced by Yates (1935) as an example of a split-plot design. The treatment structure used in the experiment was a  $3 \times 4$  full factorial, with three varieties of oats and four concentrations of nitrogen. The experimental units were arranged into six blocks, each with three whole-plots subdivided into four subplots. The varieties of oats were assigned randomly to the whole-plots and the concentrations of nitrogen to the subplots. All four concentrations of nitrogen were used on each whole-plot.

---

Orthodont

*Growth curve data on an orthodontic measurement*

---

## Description

The `Orthodont` data frame has 108 rows and 4 columns of the change in an orthodontic measurement over time for several young subjects.

## Format

This data frame contains the following columns:

**distance** a numeric vector of distances from the pituitary to the pterygomaxillary fissure (mm). These distances are measured on x-ray images of the skull.

**age** a numeric vector of ages of the subject (yr).

**Subject** an ordered factor indicating the subject on which the measurement was made. The levels are labelled M01 to M16 for the males and F01 to F13 for the females. The ordering is by increasing average distance within sex.

**Sex** a factor with levels Male and Female

## Details

Investigators at the University of North Carolina Dental School followed the growth of 27 children (16 males, 11 females) from age 8 until age 14. Every two years they measured the distance between the pituitary and the pterygomaxillary fissure, two points that are easily identified on x-ray exposures of the side of the head.

plot(Orthodont)
```

Ovary

*Counts of Ovarian Follicles***Description**

The `Ovary` data frame has 308 rows and 3 columns.

**Format**

This data frame contains the following columns:

**Mare** an ordered factor indicating the mare on which the measurement is made.

**Time** time in the estrus cycle. The data were recorded daily from 3 days before ovulation until 3 days after the next ovulation. The measurement times for each mare are scaled so that the ovulations for each mare occur at times 0 and 1.

**follicles** the number of ovarian follicles greater than 10 mm in diameter.

**Details**

Pierson and Ginther (1987) report on a study of the number of large ovarian follicles detected in different mares at several times in their estrus cycles.

**Source**

Pinheiro, J. C. and Bates, D. M. (2000), *Mixed-Effects Models in S and S-PLUS*, Springer, New York. (Appendix A.18)

Oxboys

*Heights of Boys in Oxford***Description**

The `Oxboys` data frame has 234 rows and 4 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor giving a unique identifier for each boy in the experiment

**age** a numeric vector giving the standardized age (dimensionless)

**height** a numeric vector giving the height of the boy (cm)

**Occasion** an ordered factor - the result of converting `age` from a continuous variable to a count so these slightly unbalanced data can be analyzed as balanced.

**Details**

These data are described in Goldstein (1987) as data on the height of a selection of boys from Oxford, England versus a standardized age.

---

Oxide

---

*Variability in Semiconductor Manufacturing*

---

**Description**

The Oxide data frame has 72 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Source** a factor with levels 1 and 2

**Lot** a factor giving a unique identifier for each lot.

**Wafer** a factor giving a unique identifier for each wafer within a lot.

**Site** a factor with levels 1, 2, and 3

**Thickness** a numeric vector giving the thickness of the oxide layer.

**Details**

These data are described in Littell et al. (1996, p. 155) as coming “from a passive data collection study in the semiconductor industry where the objective is to estimate the variance components to determine the assignable causes of the observed variability.” The observed response is the thickness of the oxide layer on silicon wafers, measured at three different sites of each of three wafers selected from each of eight lots sampled from the population of lots.

`pairs.compareFits` *Pairs Plot of compareFits Object*

---

## Description

Scatter plots of the values being compared are generated for each pair of coefficients in `x`. Different symbols (colors) are used for each object being compared and values corresponding to the same group are joined by a line, to facilitate comparison of fits. If only two coefficients are present, the `trellis` function `xyplot` is used; otherwise the `trellis` function `splo` is used.

## Usage

```
## S3 method for class 'compareFits'
pairs(x, subset, key, ...)
```

## Arguments

<code>x</code>	an object of class <code>compareFits</code> .
<code>subset</code>	an optional logical or integer vector specifying which rows of <code>x</code> should be used in the plots. If missing, all rows are used.
<code>key</code>	an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>splo</code> or <code>xyplot</code> ). Defaults to <code>TRUE</code> .
<code>...</code>	optional arguments passed down to the <code>trellis</code> function generating the plots.

## Value

Pairwise scatter plots of the values being compared, with different symbols (colors) used for each object under comparison.

## Author(s)

José Pinheiro and Douglas Bates

## See Also

[compareFits](#), [plot.compareFits](#), [pairs.lme](#), [pairs.lmList](#), [xyplot](#), [splo](#)

## Examples

```
fml <- lmList(Orthodont)
fm2 <- lme(Orthodont)
pairs(compareFits(coef(fml), coef(fm2)))
```

## Description

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splo` is used).

## Usage

```
## S3 method for class 'lme'
pairs(x, form, label, id, idLabels, grid, ...)
```

## Arguments

<code>x</code>	an object inheriting from class <code>"lme"</code> , representing a fitted linear mixed-effects model.
<code>form</code>	an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> , and to the left of the <code> </code> operator, must evaluate to a data frame with at least two columns. Default is <code>~ coef(.)</code> , corresponding to a pairs plot of the coefficients evaluated at the innermost level of nesting.
<code>label</code>	an optional character vector of labels for the variables in the pairs plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - value$ percentile of the appropriate chi-square distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

## End(Not run)
```

---

`pairs.lmList`

*Pairs Plot of an lmList Object*

---

**Description**

Diagnostic plots for the linear model fits corresponding to the `x` components are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. The expression on the right hand side of the formula, before a `|` operator, must evaluate to a data frame with at least two columns. If the data frame has two columns, a scatter plot of the two variables is displayed (the Trellis function `xyplot` is used). Otherwise, if more than two columns are present, a scatter plot matrix with pairwise scatter plots of the columns in the data frame is displayed (the Trellis function `splom` is used).

**Usage**

```
## S3 method for class 'lmList'
pairs(x, form, label, id, idLabels, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.
<code>form</code>	an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> , and to the left of the <code> </code> operator, must evaluate to a data frame with at least two columns. Default is <code>~ coef(.)</code> , corresponding to a pairs plot of the coefficients of <code>x</code> .

<code>label</code>	an optional character vector of labels for the variables in the pairs plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for an outlier test based on the Mahalanobis distances of the estimated random effects. Groups with random effects distances greater than the $1 - \text{value}$ percentile of the appropriate chi-square distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify points in the plot. If missing, no points are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the points identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified points. Default is the innermost grouping factor.
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is FALSE.
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

# scatter plot of estimated random effects
## Not run:
pairs(fml, ~ranef(.))

## End(Not run)
```

**Description**

The PBG data frame has 60 rows and 5 columns.

## Format

This data frame contains the following columns:

**deltaBP** a numeric vector

**dose** a numeric vector

**Run** an ordered factor with levels T5 < T4 < T3 < T2 < T1 < P5 < P3 < P2 < P4 < P1

**Treatment** a factor with levels MDL 72222 Placebo

**Rabbit** an ordered factor with levels 5 < 3 < 2 < 4 < 1

## Details

Data on an experiment to examine the effect of a antagonist MDL 72222 on the change in blood pressure experienced with increasing dosage of phenylbiguanide are described in Ludbrook (1994) and analyzed in Venables and Ripley (2002, section 10.3). Each of five rabbits was exposed to increasing doses of phenylbiguanide after having either a placebo or the HD5-antagonist MDL 72222 administered.

pdBlocked

*Positive-Definite Block Diagonal Matrix*

---

## Description

This function is a constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

## Usage

```
pdBlocked(value, form, nam, data, pdClass)
```

**Arguments**

value	an optional list with elements to be used as the <code>value</code> argument to other <code>pdMat</code> constructors. These include: <code>pdMat</code> objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
form	an optional list of one-sided linear formulas specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formulas needs to be evaluated on a <code>data.frame</code> to resolve the names they define. This argument is ignored when <code>value</code> is a list of one-sided formulas. Defaults to <code>NULL</code> .
nam	an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when <code>value</code> is a list of vector of character strings. Defaults to <code>NULL</code> .
data	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on any <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.
pdClass	an optional vector of character strings naming the <code>pdMat</code> classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when <code>value</code> is missing, or its elements are not <code>pdMat</code> objects. Defaults to <code>"pdSymm"</code> .

**Value**

a `pdBlocked` object representing a positive-definite block-diagonal matrix, also inheriting from class `pdMat`.

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 162.

**See Also**

`as.matrix.pdMat`, `coef.pdMat`, `pdClasses`, `matrix<-pdMat`

**Examples**

```
pd1 <- pdBlocked(list(diag(1:2), diag(c(0.1, 0.2, 0.3))),
                  nam = list(c("A", "B"), c("a1", "a2", "a3")))
pd1
```

pdClasses

*Positive-Definite Matrix Classes***Description**

Standard classes of positive-definite matrices (pdMat) structures available in the nlme package.

**Value**

Available standard classes:

pdSymm	general positive-definite matrix, with no additional structure
pdLogChol	general positive-definite matrix, with no additional structure, using a log-Cholesky parameterization
pdDiag	diagonal
pdIdent	multiple of an identity
pdCompSymm	compound symmetry structure (constant diagonal and constant off-diagonal elements)
pdBlocked	block-diagonal matrix, with diagonal blocks of any "atomic" pdMat class
pdNatural	general positive-definite matrix in natural parametrization (i.e. parametrized in terms of standard deviations and correlations). The underlying coefficients are not unrestricted, so this class should NOT be used for optimization.

**Note**

Users may define their own pdMat classes by specifying a constructor function and, at a minimum, methods for the functions pdConstruct, pdMatrix and coef. For examples of these functions, see the methods for classes pdSymm and pdDiag.

pdCompSymm

*Positive-Definite Matrix with Compound Symmetry Structure***Description**

This function is a constructor for the `pdCompSymm` class, representing a positive-definite matrix with compound symmetry structure (constant diagonal and constant off-diagonal elements). The underlying matrix is represented by 2 unrestricted parameters. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdCompSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector of length 2, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```
pdCompSymm(value, form, nam, data)
```

**Arguments**

- |                    |   |
|--------------------|---|
| <code>value</code> | an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector of length 2. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.   |
| <code>form</code>  | an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .   |
| <code>nam</code>   | an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .   |
| <code>data</code>  | an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called. |

**Value**

a `pdCompSymm` object representing a positive-definite matrix with compound symmetry structure, also inheriting from class `pdMat`.

pdConstruct	<i>Construct pdMat Objects</i>
-------------	--------------------------------

---

## Description

This function is an alternative constructor for the `pdMat` class associated with `object` and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of `object`.

## Usage

```
pdConstruct(object, value, form, nam, data, ...)
```

## Arguments

<code>object</code>	an object inheriting from class <code>pdMat</code> , representing a positive definite matrix.
<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.
<code>...</code>	optional arguments for some methods.

**Value**

a `pdMat` object representing a positive-definite matrix, inheriting from the same classes as `object`.

**Author(s)**

pdConstruct(pd1, diag(1:4))
```

---

`pdConstruct.pdBlocked`

*Construct pdBlocked Objects*

---

**Description**

This function give an alternative constructor for the `pdBlocked` class, representing a positive-definite block-diagonal matrix. Each block-diagonal element of the underlying matrix is itself a positive-definite matrix and is represented internally as an individual `pdMat` object. When `value` is `numeric(0)`, a list of uninitialized `pdMat` objects, a list of one-sided formulas, or a list of vectors of character strings, `object` is returned as an uninitialized `pdBlocked` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is a list of initialized `pdMat` objects, `object` will be constructed from the list obtained by applying `as.matrix` to each of the `pdMat` elements of `value`. Finally, if `value` is a list of numeric vectors, they are assumed to represent the unrestricted coefficients of the block-diagonal elements of the underlying positive-definite matrix.

**Usage**

```
## S3 method for class 'pdBlocked'
pdConstruct(object, value, form, nam, data, pdClass,
...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>"pdBlocked"</code> , representing a positive definite block-diagonal matrix.
<code>value</code>	an optional list with elements to be used as the <code>value</code> argument to other <code>pdMat</code> constructors. These include: <code>pdMat</code> objects, positive-definite matrices, one-sided linear formulas, vectors of character strings, or numeric vectors. All elements in the list must be similar (e.g. all one-sided formulas, or all numeric vectors). Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.

<code>form</code>	an optional list of one-sided linear formula specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formulas needs to be evaluated on a <code>data.frame</code> to resolve the names they defines. This argument is ignored when <code>value</code> is a list of one-sided formulas. Defaults to <code>NULL</code> .
<code>nam</code>	an optional list of vector of character strings specifying the row/column names for the block-diagonal elements of the matrix represented by <code>object</code> . Each of its components must have length equal to the dimension of the corresponding block-diagonal element and unreplicated elements. This argument is ignored when <code>value</code> is a list of vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.
<code>pdClass</code>	an optional vector of character strings naming the <code>pdMat</code> classes to be assigned to the individual blocks in the underlying matrix. If a single class is specified, it is used for all block-diagonal elements. This argument will only be used when <code>value</code> is missing, or its elements are not <code>pdMat</code> objects. Defaults to <code>"pdSymm"</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a `pdBlocked` object representing a positive-definite block-diagonal matrix, also inheriting from class `pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**Examples**

```
pd1 <- pdBlocked(list(c("A", "B"), c("a1", "a2", "a3")))
pdConstruct(pd1, list(diag(1:2), diag(c(0.1, 0.2, 0.3))))
```

pdDiag

*Diagonal Positive-Definite Matrix***Description**

This function is a constructor for the `pdDiag` class, representing a diagonal positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n$  unrestricted parameters, given by the logarithm of the square-root of the diagonal values. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdDiag` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the underlying positive-definite matrix.

**Usage**

```
pdDiag(value, form, nam, data)
```

**Arguments**

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector of length equal to the dimension of the underlying positive-definite matrix. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdDiag` object representing a diagonal positive-definite matrix, also inheriting from class `pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

pdFactor

*Square-Root Factor of a Positive-Definite Matrix*

---

## Description

A square-root factor of the positive-definite matrix represented by `object` is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $L$ .

## Usage

```
pdFactor(object)
```

## Arguments

`object` an object inheriting from class `pdMat`, representing a positive definite matrix, which must have been initialized (i.e. `length(coef(object)) > 0`).

## Value

a vector with a square-root factor of the positive-definite matrix associated with `object` stacked column-wise.

## Note

This function is used intensively in optimization algorithms and its value is returned as a vector for efficiency reasons. The `pdMatrix` function can be used to obtain square-root factors in matrix form.

```

pdIdent

*Multiple of the Identity Positive-Definite Matrix***Description**

This function is a constructor for the `pdIdent` class, representing a multiple of the identity positive-definite matrix. The matrix associated with `object` is represented by 1 unrestricted parameter, given by the logarithm of the square-root of the diagonal value. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdIdent` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric value, it is assumed to represent the unrestricted coefficient of the underlying positive-definite matrix.

**Usage**

```
pdIdent(value, form, nam, data)
```

**Arguments**

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric value. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdIdent` object representing a multiple of the identity positive-definite matrix, also inheriting from class `pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

```

---

pdLogChol

*General Positive-Definite Matrix*

---

## Description

This function is a constructor for the `pdLogChol` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n+1)/2$  unrestricted parameters, using the log-Cholesky parametrization described in Pinheiro and Bates (1996). When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdLogChol` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

## Usage

```
pdLogChol(value, form, nam, data)
```

## Arguments

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdLogChol` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

pdMat	<i>Positive-Definite Matrix</i>
-------	---------------------------------

---

**Description**

This function gives an alternative way of constructing an object inheriting from the `pdMat` class named in `pdClass`, or from `data.class(object)` if `object` inherits from `pdMat`, and is mostly used internally in other functions. See the documentation on the principal constructor function, generally with the same name as the `pdMat` class of `object`.

**Usage**

```
pdMat(value, form, nam, data, pdClass)
```

**Arguments**

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by +), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .

nam	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
data	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.
pdClass	an optional character string naming the <code>pdMat</code> class to be assigned to the returned object. This argument will only be used when <code>value</code> is not a <code>pdMat</code> object. Defaults to <code>"pdSymm"</code> .

### Value

a `pdMat` object representing a positive-definite matrix, inheriting from the class named in `pdClass`, or from `class(object)`, if `object` inherits from `pdMat`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### Examples

```
pd1 <- pdMat(diag(1:4), pdClass = "pdDiag")
pd1
```

---

pdMatrix

*Extract Matrix or Square-Root Factor from a pdMat Object*

---

### Description

The positive-definite matrix represented by `object`, or a square-root factor of it is obtained. Letting  $\Sigma$  denote a positive-definite matrix, a square-root factor of  $\Sigma$  is any square matrix  $L$  such that  $\Sigma = L'L$ . This function extracts  $S$  or  $L$ .

### Usage

```
pdMatrix(object, factor)
```

**Arguments**

- `object` an object inheriting from class `pdMat`, representing a positive definite matrix.
- `factor` an optional logical value. If `TRUE`, a square-root factor of the positive-definite matrix represented by `object` is returned; else, if `FALSE`, the positive-definite matrix is returned. Defaults to `FALSE`.

**Value**

if `fact` is `FALSE` the positive-definite matrix represented by `object` is returned; else a square-root of the positive-definite matrix is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

pd1 <- pdSymm(diag(1:4))
pdMatrix(pd1)
```

---

`pdMatrix.reStruct`    *Extract Matrix or Square-Root Factor from Components of an reStruct Object*

---

**Description**

This method function extracts the positive-definite matrices corresponding to the `pdMat` elements of `object`, or square-root factors of the positive-definite matrices.

**Usage**

```
## S3 method for class 'reStruct'
pdMatrix(object, factor)
```

**Arguments**

- `object` an object inheriting from class "`reStruct`", representing a random effects structure and consisting of a list of `pdMat` objects.
- `factor` an optional logical value. If `TRUE`, square-root factors of the positive-definite matrices represented by the elements of `object` are returned; else, if `FALSE`, the positive-definite matrices are returned. Defaults to `FALSE`.

**Value**

a list with components given by the positive-definite matrices corresponding to the elements of `object`, or square-root factors of the positive-definite matrices.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

pdMatrix(rs1)
```

---

pdNatural

*General Positive-Definite Matrix in Natural Parametrization*

---

**Description**

This function is a constructor for the `pdNatural` class, representing a general positive-definite matrix, using a natural parametrization. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n+1)/2$  parameters. Letting  $\sigma_{ij}$  denote the  $ij$ -th element of the underlying positive definite matrix and  $\rho_{ij} = \sigma_{ij}/\sqrt{\sigma_{ii}\sigma_{jj}}$ ,  $i \neq j$  denote the associated "correlations", the "natural" parameters are given by  $\sqrt{\sigma_{ii}}$ ,  $i = 1, \dots, n$  and  $\log((1 + \rho_{ij})/(1 - \rho_{ij}))$ ,  $i \neq j$ . Note that all natural parameters are individually unrestricted, but not jointly unrestricted (meaning that not all unrestricted vectors would give positive-definite matrices). Therefore, this parametrization should NOT be used for optimization. It is mostly used for deriving approximate confidence intervals on parameters following the optimization of an objective function. When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the natural parameters of the underlying positive-definite matrix.

**Usage**

```
pdNatural(value, form, nam, data)
```

**Arguments**

value	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
form	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
nam	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
data	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

**Value**

a `pdNatural` object representing a general positive-definite matrix in natural parametrization, also inheriting from class `pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. p. 162.

**Examples**

```
pdNatural(diag(1:3))
```

## Description

This function is a constructor for the `pdSymm` class, representing a general positive-definite matrix. If the matrix associated with `object` is of dimension  $n$ , it is represented by  $n(n+1)/2$  unrestricted parameters, using the matrix-logarithm parametrization described in Pinheiro and Bates (1996). When `value` is `numeric(0)`, an uninitialized `pdMat` object, a one-sided formula, or a vector of character strings, `object` is returned as an uninitialized `pdSymm` object (with just some of its attributes and its class defined) and needs to have its coefficients assigned later, generally using the `coef` or `matrix` replacement functions. If `value` is an initialized `pdMat` object, `object` will be constructed from `as.matrix(value)`. Finally, if `value` is a numeric vector, it is assumed to represent the unrestricted coefficients of the matrix-logarithm parametrization of the underlying positive-definite matrix.

## Usage

```
pdSymm(value, form, nam, data)
```

## Arguments

<code>value</code>	an optional initialization value, which can be any of the following: a <code>pdMat</code> object, a positive-definite matrix, a one-sided linear formula (with variables separated by <code>+</code> ), a vector of character strings, or a numeric vector. Defaults to <code>numeric(0)</code> , corresponding to an uninitialized object.
<code>form</code>	an optional one-sided linear formula specifying the row/column names for the matrix represented by <code>object</code> . Because factors may be present in <code>form</code> , the formula needs to be evaluated on a <code>data.frame</code> to resolve the names it defines. This argument is ignored when <code>value</code> is a one-sided formula. Defaults to <code>NULL</code> .
<code>nam</code>	an optional vector of character strings specifying the row/column names for the matrix represented by <code>object</code> . It must have length equal to the dimension of the underlying positive-definite matrix and unreplicated elements. This argument is ignored when <code>value</code> is a vector of character strings. Defaults to <code>NULL</code> .
<code>data</code>	an optional data frame in which to evaluate the variables named in <code>value</code> and <code>form</code> . It is used to obtain the levels for <code>factors</code> , which affect the dimensions and the row/column names of the underlying matrix. If <code>NULL</code> , no attempt is made to obtain information on <code>factors</code> appearing in the formulas. Defaults to the parent frame from which the function was called.

## Value

a `pdSymm` object representing a general positive-definite matrix, also inheriting from class `pdMat`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

Phenobarb

*Phenobarbital Kinetics***Description**

The `Phenobarb` data frame has 744 rows and 7 columns.

**Format**

This data frame contains the following columns:

**Subject** an ordered factor identifying the infant.

**Wt** a numeric vector giving the birth weight of the infant (kg).

**Apgar** an ordered factor giving the 5-minute Apgar score for the infant. This is an indication of health of the newborn infant.

**ApgarInd** a factor indicating whether the 5-minute Apgar score is  $< 5$  or  $\geq 5$ .

**time** a numeric vector giving the time when the sample is drawn or drug administered (hr).

**dose** a numeric vector giving the dose of drug administered ( $\mu\text{g/kg}$ ).

**conc** a numeric vector giving the phenobarbital concentration in the serum ( $\mu\text{g/L}$ ).

**Details**

Data from a pharmacokinetics study of phenobarbital in neonatal infants. During the first few days of life the infants receive multiple doses of phenobarbital for prevention of seizures. At irregular intervals blood samples are drawn and serum phenobarbital concentrations are determined. The data were originally given in Grasela and Donn(1985) and are analyzed in Boeckmann, Sheiner and Beal (1994), in Davidian and Giltinan (1995), and in Littell et al. (1996).

---

phenoModel	<i>Model function for the Phenobarb data</i>
------------	--

---

### Description

A model function for a model used with the `Phenobarb` data. This function uses compiled C code to improve execution speed.

### Usage

```
phenoModel(Subject, time, dose, lCl, lV)
```

### Arguments

<code>Subject</code>	an integer vector of subject identifiers. These should be sorted in increasing order.
<code>time</code>	numeric. A vector of the times at which the sample was drawn or the drug administered (hr).
<code>dose</code>	numeric. A vector of doses of drug administered ( <i>ug/kg</i> ).
<code>lCl</code>	numeric. A vector of values of the natural log of the clearance parameter according to <code>Subject</code> and <code>time</code> .
<code>lV</code>	numeric. A vector of values of the natural log of the effective volume of distribution according to <code>Subject</code> and <code>time</code> .

### Details

See the details section of [Phenobarb](#) for a description of the model function that `phenoModel` evaluates.

### Value

a numeric vector of predicted phenobarbital concentrations.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pixel

*X-ray pixel intensities over time***Description**

The `Pixel` data frame has 102 rows and 4 columns of data on the pixel intensities of CT scans of dogs over time

**Format**

This data frame contains the following columns:

**Dog** a factor with levels 1 to 10 designating the dog on which the scan was made

**Side** a factor with levels L and R designating the side of the dog being scanned

**day** a numeric vector giving the day post injection of the contrast on which the scan was made

**pixel** a numeric vector of pixel intensities

**Source**

Pinheiro, J. C. and Bates, D. M. (2000) *Mixed-effects Models in S and S-PLUS*, Springer.

**Examples**

```
fml <- lme(pixel ~ day + I(day^2), data = Pixel,
           random = list(Dog = ~ day, Side = ~ 1))
summary(fml)
VarCorr(fml)
```

plot.ACF

*Plot an ACF Object***Description**

an `xyplot` of the autocorrelations versus the lags, with `type = "h"`, is produced. If `alpha > 0`, curves representing the critical limits for a two-sided test of level `alpha` for the autocorrelations are added to the plot.

**Usage**

```
## S3 method for class 'ACF'
plot(x, alpha, xlab, ylab, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>ACF</code> , consisting of a data frame with two columns named <code>lag</code> and <code>ACF</code> , representing the autocorrelation values and the corresponding lags.
<code>alpha</code>	an optional numeric value with the significance level for testing if the autocorrelations are zero. Lines corresponding to the lower and upper critical values for a test of level <code>alpha</code> are added to the plot. Default is 0, in which case no lines are plotted.
<code>xlab, ylab</code>	optional character strings with the x- and y-axis labels. Default respectively to "Lag" and "Autocorrelation".
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
<code>...</code>	optional arguments passed to the <code>xyplot</code> function.

**Value**

an `xyplot` Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[ACF](#), [xyplot](#)

**Examples**

```
fml <- lme(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary)
plot(ACF(fml, maxLag = 10), alpha = 0.01)
```

---

plot.augPred

*Plot an augPred Object*

---

**Description**

A Trellis `xyplot` of predictions versus the primary covariate is generated, with a different panel for each value of the grouping factor. Predicted values are joined by lines, with different line types (colors) being used for each level of grouping. Original observations are represented by circles.

**Usage**

```
## S3 method for class 'augPred'
plot(x, key, grid, ...)
```

**Arguments**

<code>x</code>	an object of class " <code>augPred</code> ".
<code>key</code>	an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>xyplot</code> ). Defaults to <code>TRUE</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
<code>...</code>	optional arguments passed down to the <code>trellis</code> function generating the plots.

**Value**

A Trellis plot of predictions versus the primary covariate, with panels determined by the grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`augPred`, `xyplot`

**Examples**

```
fml <- lme(Orthodont)
plot(augPred(fml, level = 0:1, length.out = 2))
```

---

`plot.compareFits`      *Plot a compareFits Object*

---

**Description**

A Trellis `dotplot` of the values being compared, with different rows per group, is generated, with a different panel for each coefficient. Different symbols (colors) are used for each object being compared.

**Usage**

```
## S3 method for class 'compareFits'
plot(x, subset, key, mark, ...)
```

**Arguments**

<code>x</code>	an object of class " <code>compareFits</code> ".
<code>subset</code>	an optional logical or integer vector specifying which rows of <code>x</code> should be used in the plots. If missing, all rows are used.

key	an optional logical value, or list. If TRUE, a legend is included at the top of the plot indicating which symbols (colors) correspond to which objects being compared. If FALSE, no legend is included. If given as a list, key is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>dotplot</code> ). Defaults to TRUE.
mark	an optional numeric vector, of length equal to the number of coefficients being compared, indicating where vertical lines should be drawn in the plots. If missing, no lines are drawn.
...	optional arguments passed down to the <code>trellis</code> function generating the plots.

### Value

A Trellis `dotplot` of the values being compared, with rows determined by the groups and panels by the coefficients.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`compareFits`, `pairs.compareFits`, `dotplot`

### Examples

```
## Not run:
fm1 <- lmList(Orthodont)
fm2 <- lme(Orthodont)
plot(compareFits(coef(fm1), coef(fm2)))

## End(Not run)
```

---

plot.gls

*Plot a gls Object*

---

### Description

Diagnostic plots for the linear model fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

### Usage

```
## S3 method for class 'gls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>"gl"</code> , representing a generalized least squares fitted linear model.
<code>form</code>	an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.
<code>abline</code>	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character mode and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character mode and used to label the identified observations. Default is the innermost grouping factor.
<code>idResType</code>	an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"pearson"</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[gl](#), [xyplot](#), [bwplot](#), [histogram](#)

**Examples**

```
fml <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
          correlation = corAR1(form = ~ 1 | Mare))
# standardized residuals versus fitted values by Mare
plot(fml, resid(., type = "p") ~ fitted(.) | Mare, abline = 0)
# box-plots of residuals by Mare
plot(fml, Mare ~ resid(.))
# observed versus fitted values by Mare
plot(fml, follicles ~ fitted(.) | Mare, abline = c(0,1))
```

---

plot.intervals.lmList

*Plot lmList Confidence Intervals*

---

**Description**

A Trellis dot-plot of the confidence intervals on the linear model coefficients is generated, with a different panel for each coefficient. Rows in the dot-plot correspond to the names of the `lm` components of the `lmList` object used to produce `x`. The lower and upper confidence limits are connected by a line segment and the estimated coefficients are marked with a "+". The Trellis function `dotplot` is used in this method function.

**Usage**

```
## S3 method for class 'intervals.lmList'
plot(x, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class " <code>intervals.lmList</code> ", representing confidence intervals and estimates for the coefficients in the <code>lm</code> components of the <code>lmList</code> object used to produce <code>x</code> .
<code>...</code>	optional arguments passed to the Trellis <code>dotplot</code> function.

**Value**

a Trellis plot with the confidence intervals on the coefficients of the individual `lm` components of the `lmList` that generated `x`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`intervals.lmList`, `lmList`, `dotplot`

**Examples**

```
fml <- lmList(distance ~ age | Subject, Orthodont)
plot(intervals(fml))
```

plot.lme

*Plot an lme or nls object***Description**

Diagnostic plots for the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
## S3 method for class 'lme'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
## S3 method for class 'nls'
plot(x, form, abline, id, idLabels, idResType, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model, or from <code>nls</code> , representing an fitted nonlinear least squares model.
<code>form</code>	an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "p") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals versus fitted values, both evaluated at the innermost level of nesting.
<code>abline</code>	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized, or normalized residuals. Observations with absolute standardized (normalized) residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.

<code>idResType</code>	an optional character string specifying the type of residuals to be used in identifying outliers, when <code>id</code> is a numeric value. If "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to TRUE, else defaults to FALSE.
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

# box-plots of residuals by Subject
plot(fml, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fml, distance ~ fitted(.) | Subject, abline = c(0,1))
```

---

`plot.lmList`

*Plot an lmList Object*

---

**Description**

Diagnostic plots for the linear model fits corresponding to the  $x$  components are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display. If `form` is a one-sided formula, histograms of the variable on the right hand side of the formula, before a `|` operator, are displayed (the Trellis function `histogram` is used). If `form` is two-sided and both its left and right hand side variables are numeric, scatter plots are displayed (the Trellis function `xyplot` is used). Finally, if `form` is two-sided and its left hand side variable is a factor, box-plots of the right hand side variable by the levels of the left hand side variable are displayed (the Trellis function `bwplot` is used).

**Usage**

```
## S3 method for class 'lmList'
plot(x, form, abline, id, idLabels, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.
<code>form</code>	an optional formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>x</code> can be referenced. In addition, <code>x</code> itself can be referenced in the formula using the symbol <code>". "</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. Default is <code>resid(., type = "pool") ~ fitted(.)</code> , corresponding to a plot of the standardized residuals (using a pooled estimate for the residual standard error) versus fitted values.
<code>abline</code>	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals. Observations with absolute standardized residuals greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is <code>getGroups(x)</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot.

**See Also**

`lmList`, `predict.lm`, `xyplot`, `bwplot`, `histogram`

**Examples**

```
fml <- lmList(distance ~ age | Subject, Orthodont)
# standardized residuals versus fitted values by gender
plot(fml, resid(., type = "pool") ~ fitted(.) | Sex, abline = 0, id = 0.05)
# box-plots of residuals by Subject
plot(fml, Subject ~ resid(.))
# observed versus fitted values by Subject
plot(fml, distance ~ fitted(.) | Subject, abline = c(0,1))
```

---

plot.nffGroupedData

*Plot an nffGroupedData Object*

---

## Description

A Trellis dot-plot of the response by group is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. The Trellis function `dotplot` is used.

## Usage

```
## S3 method for class 'nffGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, panel, key,
     grid, ...)
```

## Arguments

<code>x</code>	an object inheriting from class <code>nffGroupedData</code> , representing a <code>groupedData</code> object with a factor primary covariate and a single grouping level.
<code>outer</code>	an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.
<code>inner</code>	an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.
<code>innerGroups</code>	an optional one-sided formula specifying a factor to be used for grouping the levels of the <code>inner</code> covariate. Different colors, or symbols, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.
<code>xlab</code>	an optional character string with the label for the horizontal axis. Default is the <code>y</code> elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.
<code>ylab</code>	an optional character string with the label for the vertical axis. Default is the grouping factor name.
<code>strip</code>	an optional function passed as the <code>strip</code> argument to the <code>dotplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).
<code>panel</code>	an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>dotplot</code> function.

key	an optional logical function or function. If TRUE and either inner or innerGroups are non-NULL, a legend for the different inner (innerGroups) levels is included at the top of the plot. If given as a function, it is passed as the key argument to the dotplot function. Default is TRUE is either inner or innerGroups are non-NULL and FALSE otherwise.
grid	this argument is included for consistency with the plot.nfnGroupedData method calling sequence. It is ignored in this method function.
...	optional arguments passed to the dotplot function.

**Value**

a Trellis dot-plot of the response by group.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
plot(Machines)
plot(Machines, inner = TRUE)
```

---

```
plot.nfnGroupedData
```

*Plot an nfnGroupedData Object*

---

**Description**

A Trellis plot of the response versus the primary covariate is generated. If outer variables are specified, the combination of their levels are used to determine the panels of the Trellis display. Otherwise, the levels of the grouping variable determine the panels. A scatter plot of the response versus the primary covariate is displayed in each panel, with observations corresponding to same inner group joined by line segments. The Trellis function `xyplot` is used.

**Usage**

```
## S3 method for class 'nfnGroupedData'
plot(x, outer, inner, innerGroups, xlab, ylab, strip, aspect, panel,
      key, grid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class <code>nfnGroupedData</code> , representing a <code>groupedData</code> object with a numeric primary covariate and a single grouping level.
<code>outer</code>	an optional logical value or one-sided formula, indicating covariates that are outer to the grouping factor, which are used to determine the panels of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to <code>NULL</code> , meaning that no outer covariates are to be used.
<code>inner</code>	an optional logical value or one-sided formula, indicating a covariate that is inner to the grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "inner")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.
<code>innerGroups</code>	an optional one-sided formula specifying a factor to be used for grouping the levels of the <code>inner</code> covariate. Different colors, or line types, are used for each level of the <code>innerGroups</code> factor. Default is <code>NULL</code> , meaning that no <code>innerGroups</code> covariate is present.
<code>xlab, ylab</code>	optional character strings with the labels for the plot. Default is the corresponding elements of <code>attr(object, "labels")</code> and <code>attr(object, "units")</code> pasted together.
<code>strip</code>	an optional function passed as the <code>strip</code> argument to the <code>xyplot</code> function. Default is <code>strip.default(..., style = 1)</code> (see <code>trellis.args</code> ).
<code>aspect</code>	an optional character string indicating the aspect ratio for the plot passed as the <code>aspect</code> argument to the <code>xyplot</code> function. Default is <code>"xy"</code> (see <code>trellis.args</code> ).
<code>panel</code>	an optional function used to generate the individual panels in the Trellis display, passed as the <code>panel</code> argument to the <code>xyplot</code> function.
<code>key</code>	an optional logical function or function. If <code>TRUE</code> and <code>innerGroups</code> is non- <code>NULL</code> , a legend for the different <code>innerGroups</code> levels is included at the top of the plot. If given as a function, it is passed as the <code>key</code> argument to the <code>xyplot</code> function. Default is <code>TRUE</code> if <code>innerGroups</code> is non- <code>NULL</code> and <code>FALSE</code> otherwise.
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>TRUE</code> .
<code>...</code>	optional arguments passed to the <code>xyplot</code> function.

**Value**

a Trellis plot of the response versus the primary covariate.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

plot.nmGroupedData *Plot an nmGroupedData Object*

---

## Description

The groupedData object is summarized by the values of the displayLevel grouping factor (or the combination of its values and the values of the covariate indicated in preserve, if any is present). The collapsed data is used to produce a new groupedData object, with grouping factor given by the displayLevel factor, which is plotted using the appropriate plot method for groupedData objects with single level of grouping.

## Usage

```
## S3 method for class 'nmGroupedData'
plot(x, collapseLevel, displayLevel, outer, inner,
     preserve, FUN, subset, key, grid, ...)
```

## Arguments

x	an object inheriting from class nmGroupedData, representing a groupedData object with multiple grouping factors.
collapseLevel	an optional positive integer or character string indicating the grouping level to use when collapsing the data. Level values increase from outermost to innermost grouping. Default is the highest or innermost level of grouping.
displayLevel	an optional positive integer or character string indicating the grouping level to use for determining the panels in the Trellis display, when outer is missing. Default is collapseLevel.
outer	an optional logical value or one-sided formula, indicating covariates that are outer to the displayLevel grouping factor, which are used to determine the panels of the Trellis plot. If equal to TRUE, the displayLevel element attr(object, "outer") is used to indicate the outer covariates. An outer covariate is invariant within the sets of rows defined by the grouping factor. Ordering of the groups is done in such a way as to preserve adjacency of groups with the same value of the outer variables. Defaults to NULL, meaning that no outer covariates are to be used.

<code>inner</code>	an optional logical value or one-sided formula, indicating a covariate that is inner to the <code>displayLevel</code> grouping factor, which is used to associate points within each panel of the Trellis plot. If equal to <code>TRUE</code> , <code>attr(object, "outer")</code> is used to indicate the inner covariate. An inner covariate can change within the sets of rows defined by the grouping factor. Defaults to <code>NULL</code> , meaning that no inner covariate is present.
<code>preserve</code>	an optional one-sided formula indicating a covariate whose levels should be preserved when collapsing the data according to the <code>collapseLevel</code> grouping factor. The collapsing factor is obtained by pasting together the levels of the <code>collapseLevel</code> grouping factor and the values of the covariate to be preserved. Default is <code>NULL</code> , meaning that no covariates need to be preserved.
<code>FUN</code>	an optional summary function or a list of summary functions to be used for collapsing the data. The function or functions are applied only to variables in <code>object</code> that vary within the groups defined by <code>collapseLevel</code> . Invariant variables are always summarized by group using the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the data such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any non-invariant variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
<code>subset</code>	an optional named list. Names can be either positive integers representing grouping levels, or names of grouping factors. Each element in the list is a vector indicating the levels of the corresponding grouping factor to be used for plotting the data. Default is <code>NULL</code> , meaning that all levels are used.
<code>key</code>	an optional logical value, or list. If <code>TRUE</code> , a legend is included at the top of the plot indicating which symbols (colors) correspond to which prediction levels. If <code>FALSE</code> , no legend is included. If given as a list, <code>key</code> is passed down as an argument to the <code>trellis</code> function generating the plots ( <code>xyplot</code> ). Defaults to <code>TRUE</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>TRUE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a Trellis display of the data collapsed over the values of the `collapseLevel` grouping factor and grouped according to the `displayLevel` grouping factor.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

plot.ranef.lme	<i>Plot a ranef.lme Object</i>
----------------	--------------------------------

---

**Description**

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (factor or ordered) variables.

**Usage**

```
## S3 method for class 'ranef.lme'
plot(x, form, omitFixed, level, grid, control, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class " <a href="#">"ranef.lme"</a> ", representing the estimated coefficients or estimated random effects for the <code>lme</code> object from which it was produced.
<code>form</code>	an optional formula specifying the desired type of plot. If given as a one-sided formula, a <code>dotplot</code> of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in <code>form</code> is returned. Single factors ( <code>~g</code> ) or crossed factors ( <code>~g1*g2</code> ) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in <code>x</code> separated by <code>+</code> . A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is <code>NULL</code> , in which case the row names of the random effects (coefficients) are used.
<code>omitFixed</code>	an optional logical value indicating whether columns with values that are constant across groups should be omitted. Default is <code>TRUE</code> .
<code>level</code>	an optional integer value giving the level of grouping to be used for <code>x</code> . Only used when <code>x</code> is a list with different components for each grouping level. Defaults to the highest or innermost level of grouping.

<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in <code>form</code> . Default is <code>FALSE</code> .
<code>control</code>	an optional list with control values for the plot, when <code>form</code> is given as a two-sided formula. The control values are referenced by name in the <code>control</code> list and only the ones to be modified from the default need to be specified. Available values include: <code>drawLine</code> , a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is <code>TRUE</code> ); <code>span.loess</code> , used as the <code>span</code> argument in the call to <code>panel.loess</code> (default is <code>2/3</code> ); <code>degree.loess</code> , used as the <code>degree</code> argument in the call to <code>panel.loess</code> (default is <code>1</code> ); <code>cex.axis</code> , the character expansion factor for the x-axis (default is <code>0.8</code> ); <code>srt.axis</code> , the rotation factor for the x-axis (default is <code>0</code> ); and <code>mgp.axis</code> , the margin parameters for the x-axis (default is <code>c(2, 0.5, 0)</code> ).
<code>...</code>	optional arguments passed to the Trellis <code>dotplot</code> function.

### Value

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

## End(Not run)
```

---

`plot.ranef.lmList` *Plot a ranef.lmList Object*

---

### Description

If `form` is missing, or is given as a one-sided formula, a Trellis dot-plot of the random effects is generated, with a different panel for each random effect (coefficient). Rows in the dot-plot are determined by the `form` argument (if not missing) or by the row names of the random effects (coefficients). If a single factor is specified in `form`, its levels determine the dot-plot rows (with possibly multiple dots per row); otherwise, if `form` specifies a crossing of factors, the dot-plot rows are determined by all combinations of the levels of the individual factors in the formula. The Trellis function `dotplot` is used in this method function.

If `form` is a two-sided formula, a Trellis display is generated, with a different panel for each variable listed in the right hand side of `form`. Scatter plots are generated for numeric variables and boxplots are generated for categorical (`factor` or `ordered`) variables.

**Usage**

```
## S3 method for class 'ranef.lmList'
plot(x, form, grid, control, ...)
```

**Arguments**

x	an object inheriting from class " <a href="#">ranef.lmList</a> ", representing the estimated coefficients or estimated random effects for the <code>lmList</code> object from which it was produced.
form	an optional formula specifying the desired type of plot. If given as a one-sided formula, a <code>dotplot</code> of the estimated random effects (coefficients) grouped according to all combinations of the levels of the factors named in <code>form</code> is returned. Single factors ( <code>~g</code> ) or crossed factors ( <code>~g1*g2</code> ) are allowed. If given as a two-sided formula, the left hand side must be a single random effects (coefficient) and the right hand side is formed by covariates in <code>x</code> separated by <code>+</code> . A Trellis display of the random effect (coefficient) versus the named covariates is returned in this case. Default is <code>NULL</code> , in which case the row names of the random effects (coefficients) are used.
grid	an optional logical value indicating whether a grid should be added to plot. Only applies to plots associated with two-sided formulas in <code>form</code> . Default is <code>FALSE</code> .
control	an optional list with control values for the plot, when <code>form</code> is given as a two-sided formula. The control values are referenced by name in the <code>control</code> list and only the ones to be modified from the default need to be specified. Available values include: <code>drawLine</code> , a logical value indicating whether a loess smoother should be added to the scatter plots and a line connecting the medians should be added to the boxplots (default is <code>TRUE</code> ); <code>span.loess</code> , used as the <code>span</code> argument in the call to <code>panel.loess</code> (default is <code>2/3</code> ); <code>degree.loess</code> , used as the <code>degree</code> argument in the call to <code>panel.loess</code> (default is <code>1</code> ); <code>cex.axis</code> , the character expansion factor for the x-axis (default is <code>0.8</code> ); <code>srt.axis</code> , the rotation factor for the x-axis (default is <code>0</code> ); and <code>mgp.axis</code> , the margin parameters for the x-axis (default is <code>c(2, 0.5, 0)</code> ).
...	optional arguments passed to the Trellis <code>dotplot</code> function.

**Value**

a Trellis plot of the estimated random-effects (coefficients) versus covariates, or groups.

```

---

plot.Variogram      *Plot a Variogram Object*

---

### Description

an `xyplot` of the semi-variogram versus the distances is produced. If `smooth = TRUE`, a loess smoother is added to the plot. If `showModel = TRUE` and `x` includes an `"modelVariog"` attribute, the corresponding semi-variogram is added to the plot.

### Usage

```
## S3 method for class 'Variogram'
plot(x, smooth, showModel, sigma, span, xlab,
     ylab, type, ylim, grid, ...)
```

### Arguments

<code>x</code>	an object inheriting from class <code>"Variogram"</code> , consisting of a data frame with two columns named <code>variog</code> and <code>dist</code> , representing the semi-variogram values and the corresponding distances.
<code>smooth</code>	an optional logical value controlling whether a loess smoother should be added to the plot. Defaults to <code>TRUE</code> , when <code>showModel</code> is <code>FALSE</code> .
<code>showModel</code>	an optional logical value controlling whether the semi-variogram corresponding to an <code>"modelVariog"</code> attribute of <code>x</code> , if any is present, should be added to the plot. Defaults to <code>TRUE</code> , when the <code>"modelVariog"</code> attribute is present.
<code>sigma</code>	an optional numeric value used as the height of a horizontal line displayed in the plot. Can be used to represent the process standard deviation. Default is <code>NULL</code> , implying that no horizontal line is drawn.
<code>span</code>	an optional numeric value with the smoothing parameter for the loess fit. Default is 0.6.
<code>xlab, ylab</code>	optional character strings with the x- and y-axis labels. Default respectively to <code>"Distance"</code> and <code>"SemiVariogram"</code> .
<code>type</code>	an optional character indicating the type of plot. Defaults to <code>"p"</code> .
<code>ylim</code>	an optional numeric vector with the limits for the y-axis. Defaults to <code>c(0, max(x\$variog))</code> .
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis <code>xyplot</code> function.

### Value

an `xyplot` Trellis plot.

```

---

pooledSD

*Extract Pooled Standard Deviation*

---

**Description**

The pooled estimated standard deviation is obtained by adding together the residual sum of squares for each non-null element of `object`, dividing by the sum of the corresponding residual degrees-of-freedom, and taking the square-root.

**Usage**

```
pooledSD(object)
```

**Arguments**

`object`                    an object inheriting from class `lmList`.

**Value**

the pooled standard deviation for the non-null elements of `object`, with an attribute `df` with the number of degrees-of-freedom used in the estimation.

predict.gls

*Predictions from a gls Object*

---

## Description

The predictions for the linear model represented by `object` are obtained at the covariate values defined in `newdata`.

## Usage

```
## S3 method for class 'gls'
predict(object, newdata, na.action, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>gls</code> ", representing a generalized least squares fitted linear model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the linear model must be present in the data frame. If missing, the fitted values are returned.
<code>na.action</code>	a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

a vector with the predicted values.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

predict.lme	<i>Predictions from an lme Object</i>
-------------	---------------------------------------

---

**Description**

The predictions at level  $i$  are obtained by adding together the population predictions (based only on the fixed effects estimates) and the estimated contributions of the random effects to the predictions at grouping levels less or equal to  $i$ . The resulting values estimate the best linear unbiased predictions (BLUPs) at level  $i$ . If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
## S3 method for class 'lme'
predict(object, newdata, level, asList, na.action, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the fixed and random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> .
<code>na.action</code>	a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`lme`, `fitted.lme`

**Examples**

```
fml <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
newOrth <- data.frame(Sex = c("Male", "Male", "Female", "Female", "Male", "Male"),
                      age = c(15, 20, 10, 12, 2, 4),
                      Subject = c("M01", "M01", "F30", "F30", "M04", "M04"))
predict(fml, newOrth, level = 0:1)
```

predict.lmList

*Predictions from an lmList Object***Description**

If the grouping factor corresponding to `object` is included in `newdata`, the data frame is partitioned according to the grouping factor levels; else, `newdata` is repeated for all `lm` components. The predictions and, optionally, the standard errors for the predictions, are obtained for each `lm` component of `object`, using the corresponding element of the partitioned `newdata`, and arranged into a list with as many components as `object`, or combined into a single vector or data frame (if `se.fit=TRUE`).

**Usage**

```
## S3 method for class 'lmList'
predict(object, newdata, subset, pool, asList, se.fit, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the <code>object</code> model formula must be present in the data frame. If missing, the same data frame used to produce <code>object</code> is used.
<code>subset</code>	an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the predictions are to be extracted. Default is <code>NULL</code> , in which case all components are used.
<code>asList</code>	an optional logical value. If <code>TRUE</code> , the returned object is a list with the predictions split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .
<code>pool</code>	an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> .
<code>se.fit</code>	an optional logical value indicating whether pointwise standard errors should be computed along with the predictions. Default is <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with components given by the predictions (and, optionally, the standard errors for the predictions) from each `lm` component of `object`, a vector with the predictions from all `lm` components of `object`, or a data frame with columns given by the predictions and their corresponding standard errors.

**Examples**

```
fml <- lmList(distance ~ age | Subject, Orthodont)
predict(fml, se.fit = TRUE)
```

---

predict.nlme

*Predictions from an nlme Object*

---

**Description**

The predictions at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters. If group values not included in the original grouping factors are present in `newdata`, the corresponding predictions will be set to NA for levels greater or equal to the level at which the unknown groups occur.

**Usage**

```
## S3 method for class 'nlme'
predict(object, newdata, level, asList, na.action,
        naPattern, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>nlme</code> ", representing a fitted nonlinear mixed-effects model.
<code>newdata</code>	an optional data frame to be used for obtaining the predictions. All variables used in the nonlinear model, the fixed and the random effects models, as well as the grouping factors, must be present in the data frame. If missing, the fitted values are returned.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the predictions split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> .
<code>na.action</code>	a function that indicates what should happen when <code>newdata</code> contains NAs. The default action ( <code>na.fail</code> ) causes the function to print an error message and terminate if there are any incomplete observations.
<code>naPattern</code>	an expression or formula object, specifying which returned values are to be regarded as missing.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the predictions split by groups (`asList = TRUE`) or a vector with the predictions (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the predictions at different levels and the grouping factors.

[nlme](#), [fitted.lme](#)

**Examples**

```
fml <- nlme(height ~ SSasyp(age, Asym, R0, lrc),
            data = Loblolly,
            fixed = Asym + R0 + lrc ~ 1,
            random = Asym ~ 1,
            start = c(Asym = 103, R0 = -8.5, lrc = -3.3))
newLoblolly <- data.frame(age = c(5,10,15,20,25,30),
                          Seed = rep(301,6))
predict(fml, newLoblolly, level = 0:1)
```

---

```
print.summary.pdMat
```

*Print a summary.pdMat Object*

---

**Description**

The standard deviations and correlations associated with the positive-definite matrix represented by `object` (considered as a variance-covariance matrix) are printed, together with the formula and the grouping level associated `object`, if any are present.

**Usage**

```
## S3 method for class 'summary.pdMat'
print(x, sigma, rdig, Level, resid, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class " <a href="#">summary.pdMat</a> ", generally resulting from applying <a href="#">summary</a> to an object inheriting from class " <a href="#">pdMat</a> ".
<code>sigma</code>	an optional numeric value used as a multiplier for the square-root factor of the positive-definite matrix represented by <code>object</code> (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.
<code>rdig</code>	an optional integer value with the number of significant digits to be used in printing correlations. Defaults to 3.

Level	an optional character string with a description of the grouping level associated with <code>object</code> (generally corresponding to levels of grouping in a mixed-effects model). Defaults to <code>NULL</code> .
resid	an optional logical value. If <code>TRUE</code> an extra row with the "residual" standard deviation given in <code>sigma</code> will be included in the output. Defaults to <code>FALSE</code> .
...	optional arguments passed to <code>print.default</code> ; see the documentation on that method function.

```

---

<code>print.varFunc</code>	<i>Print a varFunc Object</i>
----------------------------	-------------------------------

---

**Description**

The class and the coefficients associated with `x` are printed.

**Usage**

```
## S3 method for class 'varFunc'
print(x, ...)
```

**Arguments**

<code>x</code>	an object inheriting from class " <a href="#">varFunc</a> ", representing a variance function structure.
...	optional arguments passed to <code>print.default</code> ; see the documentation on that method function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varPower(0.3, form = ~age)
vf1 <- Initialize(vf1, Orthodont)
print(vf1)
```

qqnorm.gls

*Normal Plot of Residuals from a gls Object***Description**

Diagnostic plots for assessing the normality of residuals the generalized least squares fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
## S3 method for class 'gls'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

<code>y</code>	an object inheriting from class " <code>gls</code> ", representing a generalized least squares fitted model.
<code>form</code>	an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol " <code>.</code> ". Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals.
<code>abline</code>	an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.
<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - \text{value}/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default depends on the type of Trellis plot used: if <code>xyplot</code> defaults to <code>TRUE</code> , else defaults to <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot for assessing normality of residuals.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

qqnorm.lme

*Normal Plot of Residuals or Random Effects from an lme Object*

---

**Description**

Diagnostic plots for assessing the normality of residuals and random effects in the linear mixed-effects fit are obtained. The `form` argument gives considerable flexibility in the type of plot specification. A conditioning expression (on the right side of a `|` operator) always implies that different panels are used for each level of the conditioning factor, according to a Trellis display.

**Usage**

```
## S3 method for class 'lme'
qqnorm(y, form, abline, id, idLabels, grid, ...)
```

**Arguments**

- |                     |   |
|---------------------|---|
| <code>y</code>      | an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model or from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> objects, or from class " <code>lm</code> ", representing a fitted linear model, or from class " <code>nls</code> ", representing a nonlinear least squares fitted model.   |
| <code>form</code>   | an optional one-sided formula specifying the desired type of plot. Any variable present in the original data frame used to obtain <code>y</code> can be referenced. In addition, <code>y</code> itself can be referenced in the formula using the symbol <code>"."</code> . Conditional expressions on the right of a <code> </code> operator can be used to define separate panels in a Trellis display. The expression on the right hand side of <code>form</code> and to the left of a <code> </code> operator must evaluate to a residuals vector, or a random effects matrix. Default is <code>~ resid(., type = "p")</code> , corresponding to a normal plot of the standardized residuals evaluated at the innermost level of nesting. |
| <code>abline</code> | an optional numeric value, or numeric vector of length two. If given as a single value, a horizontal line will be added to the plot at that coordinate; else, if given as a vector, its values are used as the intercept and slope for a line added to the plot. If missing, no lines are added to the plot.  |

<code>id</code>	an optional numeric value, or one-sided formula. If given as a value, it is used as a significance level for a two-sided outlier test for the standardized residuals (random effects). Observations with absolute standardized residuals (random effects) greater than the $1 - value/2$ quantile of the standard normal distribution are identified in the plot using <code>idLabels</code> . If given as a one-sided formula, its right hand side must evaluate to a logical, integer, or character vector which is used to identify observations in the plot. If missing, no observations are identified.
<code>idLabels</code>	an optional vector, or one-sided formula. If given as a vector, it is converted to character and used to label the observations identified according to <code>id</code> . If given as a one-sided formula, its right hand side must evaluate to a vector which is converted to character and used to label the identified observations. Default is the innermost grouping factor.
<code>grid</code>	an optional logical value indicating whether a grid should be added to plot. Default is <code>FALSE</code> .
<code>...</code>	optional arguments passed to the Trellis plot function.

**Value**

a diagnostic Trellis plot for assessing normality of residuals or random effects.

**Author(s)**

Quinidine	<i>Quinidine Kinetics</i>
-----------	---------------------------

---

**Description**

The Quinidine data frame has 1471 rows and 14 columns.

### Format

This data frame contains the following columns:

**Subject** a factor identifying the patient on whom the data were collected.

**time** a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.

**conc** a numeric vector giving the serum quinidine concentration (mg/L).

**dose** a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.

**interval** a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.

**Age** a numeric vector giving the age of the subject on entry to the study (yr).

**Height** a numeric vector giving the height of the subject on entry to the study (in.).

**Weight** a numeric vector giving the body weight of the subject (kg).

**Race** a factor with levels *Caucasian*, *Latin*, and *Black* identifying the race of the subject.

**Smoke** a factor with levels *no* and *yes* giving smoking status at the time of the measurement.

**Ethanol** a factor with levels *none*, *current*, *former* giving ethanol (alcohol) abuse status at the time of the measurement.

**Heart** a factor with levels *No/Mild*, *Moderate*, and *Severe* indicating congestive heart failure for the subject.

**Creatinine** an ordered factor with levels *< 50* *< = 50* indicating the creatine clearance (mg/min).

**glyco** a numeric vector giving the alpha-1 acid glycoprotein concentration (mg/dL). Often measured at the same time as the quinidine concentration.

### Details

Verme et al. (1992) analyze routine clinical data on patients receiving the drug quinidine as a treatment for cardiac arrhythmia (atrial fibrillation of ventricular arrhythmias). All patients were receiving oral quinidine doses. At irregular intervals blood samples were drawn and serum concentrations of quinidine were determined. These data are analyzed in several publications, including Davidian and Giltinan (1995, section 9.3).

---

 quinModel

---

*Model function for the Quinidine data*

---

## Description

A model function for a model used with the `Quinidine` data. This function calls compiled C code.

## Usage

```
quinModel(Subject, time, conc, dose, interval, lV, lKa, lCl)
```

## Arguments

<code>Subject</code>	a factor identifying the patient on whom the data were collected.
<code>time</code>	a numeric vector giving the time (hr) at which the drug was administered or the blood sample drawn. This is measured from the time the patient entered the study.
<code>conc</code>	a numeric vector giving the serum quinidine concentration (mg/L).
<code>dose</code>	a numeric vector giving the dose of drug administered (mg). Although there were two different forms of quinidine administered, the doses were adjusted for differences in salt content by conversion to milligrams of quinidine base.
<code>interval</code>	a numeric vector giving the when the drug has been given at regular intervals for a sufficiently long period of time to assume steady state behavior, the interval is recorded.
<code>lV</code>	numeric. A vector of values of the natural log of the effective volume of distribution according to <code>Subject</code> and <code>time</code> .
<code>lKa</code>	numeric. A vector of values of the natural log of the absorption rate constant according to <code>Subject</code> and <code>time</code> .
<code>lCl</code>	numeric. A vector of values of the natural log of the clearance parameter according to <code>Subject</code> and <code>time</code> .

## Details

See the details section of [Quinidine](#) for a description of the model function that `quinModel` evaluates.

## Value

a numeric vector of predicted quinidine concentrations.

Rail

---

*Evaluation of Stress in Railway Rails*

---

### Description

The `Rail` data frame has 18 rows and 2 columns.

### Format

This data frame contains the following columns:

**Rail** an ordered factor identifying the rail on which the measurement was made.

**travel** a numeric vector giving the travel time for ultrasonic head-waves in the rail (nanoseconds).  
The value given is the original travel time minus 36,100 nanoseconds.

### Details

Devore (2000, Example 10.10, p. 427) cites data from an article in *Materials Evaluation* on “a study of travel time for a certain type of wave that results from longitudinal stress of rails used for railroad track.”

random.effects

---

*Extract Random Effects*

---

### Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `lmList` and `lme`.

### Usage

```
random.effects(object, ...)
ranef(object, ...)
```

### Arguments

`object` any fitted model object from which random effects estimates can be extracted.  
`...` some methods for this generic function require additional arguments.

### Value

will depend on the method function used; see the appropriate documentation.

## References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

## See Also

## Examples

```
## see the method function documentation
```

---

<code>ranef.lme</code>	<i>Extract lme Random Effects</i>
------------------------	-----------------------------------

---

## Description

The estimated random effects at level  $i$  are represented as a data frame with rows given by the different groups at that level and columns given by the random effects. If a single level of grouping is specified, the returned object is a data frame; else, the returned object is a list of such data frames. Optionally, the returned data frame(s) may be augmented with covariates summarized over groups.

## Usage

```
## S3 method for class 'lme'
ranef(object, augFrame, level, data, which, FUN,
       standard, omitGroupingFactor, subset, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
<code>augFrame</code>	an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in <code>data</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .
<code>level</code>	an optional vector of positive integers giving the levels of grouping to be used in extracting the random effects from an object with multiple nested grouping levels. Defaults to all levels of grouping.
<code>data</code>	an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .
<code>which</code>	an optional positive integer vector specifying which columns of <code>data</code> should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .
<code>FUN</code>	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing <code>data</code> by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame

such as `ordered`, `factor`, or `numeric`. The indicated function will be applied to any group-varying variables of that class. The default functions to be used are `mean` for numeric factors, and `Mode` for both `factor` and `ordered`. The `Mode` function, defined internally in `gsummary`, returns the modal or most popular value of the variable. It is different from the `mode` function that returns the S-language mode of the variable.

<code>standard</code>	an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the estimate of the standard deviation of that group of random effects). Defaults to <code>FALSE</code> .
<code>omitGroupingFactor</code>	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .
<code>subset</code>	an optional expression indicating for which rows the random effects should be extracted.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame, or list of data frames, with the estimated random effects at the grouping level(s) specified in `level` and, optionally, other covariates summarized over groups. The returned object inherits from classes `random.effects.lme` and `data.frame`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### References

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer, esp. pp. 100, 461.

### See Also

`coef.lme`, `gsummary`, `lme`, `plot.ranef.lme`, `random.effects`

### Examples

```
fml <- lme(distance ~ age, Orthodont, random = ~ age | Subject)
ranef(fml)
random.effects(fml)           # same as above
random.effects(fml, augFrame = TRUE)
```

---

ranef.lmList	<i>Extract lmList Random Effects</i>
--------------	--------------------------------------

---

## Description

The difference between the individual `lm` components coefficients and their average is calculated.

## Usage

```
## S3 method for class 'lmList'
ranef(object, augFrame, data, which, FUN, standard,
      omitGroupingFactor, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>lmList</code> ", representing a list of <code>lm</code> objects with a common model.
<code>augFrame</code>	an optional logical value. If <code>TRUE</code> , the returned data frame is augmented with variables defined in <code>data</code> ; else, if <code>FALSE</code> , only the coefficients are returned. Defaults to <code>FALSE</code> .
<code>data</code>	an optional data frame with the variables to be used for augmenting the returned data frame when <code>augFrame = TRUE</code> . Defaults to the data frame used to fit <code>object</code> .
<code>which</code>	an optional positive integer vector specifying which columns of <code>data</code> should be used in the augmentation of the returned data frame. Defaults to all columns in <code>data</code> .
<code>FUN</code>	an optional summary function or a list of summary functions to be applied to group-varying variables, when collapsing <code>data</code> by groups. Group-invariant variables are always summarized by the unique value that they assume within that group. If <code>FUN</code> is a single function it will be applied to each non-invariant variable by group to produce the summary for that variable. If <code>FUN</code> is a list of functions, the names in the list should designate classes of variables in the frame such as <code>ordered</code> , <code>factor</code> , or <code>numeric</code> . The indicated function will be applied to any group-varying variables of that class. The default functions to be used are <code>mean</code> for numeric factors, and <code>Mode</code> for both <code>factor</code> and <code>ordered</code> . The <code>Mode</code> function, defined internally in <code>gsummary</code> , returns the modal or most popular value of the variable. It is different from the <code>mode</code> function that returns the S-language mode of the variable.
<code>standard</code>	an optional logical value indicating whether the estimated random effects should be "standardized" (i.e. divided by the corresponding estimated standard error). Defaults to <code>FALSE</code> .
<code>omitGroupingFactor</code>	an optional logical value. When <code>TRUE</code> the grouping factor itself will be omitted from the group-wise summary of <code>data</code> but the levels of the grouping factor will continue to be used as the row names for the returned data frame. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the differences between the individual `lm` coefficients in `object` and their average.

RatPupWeight

*The weight of rat pups*

---

**Description**

The `RatPupWeight` data frame has 322 rows and 5 columns.

**Format**

This data frame contains the following columns:

**weight** a numeric vector

**sex** a factor with levels Male Female

**Litter** an ordered factor with levels 9 < 8 < 7 < 4 < 2 < 10 < 1 < 3 < 5 < 6 < 21 < 22 < 24 < 27 < 26 < 25 < 23 < 17 < 11 < 14 < 13 < 15 < 16 < 20 < 19 < 18 < 12

**Lsize** a numeric vector

**Treatment** an ordered factor with levels Control < Low < High

`recalc`*Recalculate Condensed Linear Model Object*

---

## Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `corStruct`, `modelStruct`, `reStruct`, and `varFunc`.

## Usage

```
recalc(object, conLin, ...)
```

## Arguments

<code>object</code>	any object which induces a recalculation of the condensed linear model object <code>conLin</code> .
<code>conLin</code>	a condensed linear model object, consisting of a list with components <code>"Xy"</code> , corresponding to a regression matrix (X) combined with a response vector (y), and <code>"logLik"</code> , corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic can take additional arguments.

## Value

the recalculated condensed linear model object.

## Note

This function is only used inside model fitting functions, such as `lme` and `gls`, that require recalculation of a condensed linear model object.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[recalc.corStruct](#), [recalc.modelStruct](#), [recalc.reStruct](#), [recalc.varFunc](#)

## Examples

```
## see the method function documentation
```

---

recalc.corStruct	<i>Recalculate for corStruct Object</i>
------------------	---

---

## Description

This method function pre-multiplies the "Xy" component of `conLin` by the transpose square-root factor(s) of the correlation matrix (matrices) associated with `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "logLik" component of `conLin`.

## Usage

```
## S3 method for class 'corStruct'
recalc(object, conLin, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>corStruct</code> ", representing a correlation structure.
<code>conLin</code>	a condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

the recalculated condensed linear model object.

## Note

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow correlated error terms.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## See Also

[corFactor](#), [logLik.corStruct](#)

---

`recalc.modelStruct` *Recalculate for a modelStruct Object*

---

### Description

This method function recalculates the condensed linear model object using each element of `object` sequentially from last to first.

### Usage

```
## S3 method for class 'modelStruct'
recalc(object, conLin, ...)
```

### Arguments

<code>object</code>	an object inheriting from class "modelStruct", representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components "Xy", corresponding to a regression matrix (X) combined with a response vector (y), and "logLik", corresponding to the log-likelihood of the underlying model. Defaults to <code>attr(object, "conLin")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the recalculated condensed linear model object.

### Note

This method function is generally only used inside model fitting functions, such as `lme` and `gls`, that allow model components, such as correlated error terms and variance functions.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[recalc.corStruct](#), [recalc.reStruct](#), [recalc.varFunc](#)

---

recalc.reStruct	<i>Recalculate for an reStruct Object</i>
-----------------	---

---

### Description

The log-likelihood, or restricted log-likelihood, of the Gaussian linear mixed-effects model represented by `object` and `conLin` (assuming spherical within-group covariance structure), evaluated at `coef(object)` is calculated and added to the `logLik` component of `conLin`. The `settings` attribute of `object` determines whether the log-likelihood, or the restricted log-likelihood, is to be calculated. The computational methods for the (restricted) log-likelihood calculations are described in Bates and Pinheiro (1998).

### Usage

```
## S3 method for class 'reStruct'
recalc(object, conLin, ...)
```

### Arguments

<code>object</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>conLin</code>	a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

the condensed linear model with its `logLik` component updated.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`logLik`, `lme`, `recalc`, `reStruct`

---

recalc.varFunc	<i>Recalculate for varFunc Object</i>
----------------	---------------------------------------

---

### Description

This method function pre-multiplies the "`Xy`" component of `conLin` by a diagonal matrix with diagonal elements given by the weights corresponding to the variance structure represented by `object` and adds the log-likelihood contribution of `object`, given by `logLik(object)`, to the "`logLik`" component of `conLin`.

**Usage**

```
## S3 method for class 'varFunc'
recalc(object, conLin, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>varFunc</code> ", representing a variance function structure.
<code>conLin</code>	a condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( <code>X</code> ) combined with a response vector ( <code>y</code> ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying model.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

the recalculated condensed linear model object.

**Note**

This method function is only used inside model fitting functions, such as `lme` and `gls`, that allow heteroscedastic error terms.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`recalc`, `varWeights`, `logLik.varFunc`

---

residuals.gls

*Extract gls Residuals*

---

### Description

The residuals for the linear model represented by `object` are extracted.

### Usage

```
## S3 method for class 'gls'
residuals(object, type, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class <code>"glS"</code> , representing a generalized least squares fitted linear model, or from class <code>gnls</code> , representing a generalized nonlinear least squares fitted linear model.
<code>type</code>	an optional character string specifying the type of residuals to be used. If <code>"response"</code> , the <code>"raw"</code> residuals (observed - fitted) are used; else, if <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"response"</code> .
<code>...</code>	some methods for this generic function require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the linear model represented by `object`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[glS](#)

**Examples**

```
fml <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
           correlation = corAR1(form = ~ 1 | Mare))
residuals(fml)
```

---

```
residuals.glsStruct
```

*Calculate glsStruct Residuals*

---

**Description**

The residuals for the linear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'glSStruct'
residuals(object, glsFit, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>glsStruct</code> ", representing a list of linear model components, such as <code>corStruct</code> and " <code>varFunc</code> " objects.
<code>glsFit</code>	an optional list with components <code>logLik</code> (log-likelihood), <code>beta</code> (coefficients), <code>sigma</code> (standard deviation for error term), <code>varBeta</code> (coefficients' covariance matrix), <code>fitted</code> (fitted values), and <code>residuals</code> (residuals). Defaults to <code>attr(object, "glsFit")</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the linear model represented by `object`.

**Note**

This method function is primarily used inside `gls` and `residuals.gls`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`gls`, `glsStruct`, `residuals.gls`, `fitted.glsStruct`

---

```
residuals.gnlsStruct
```

*Calculate gnlsStruct Residuals*

---

**Description**

The residuals for the nonlinear model represented by `object` are extracted.

**Usage**

```
## S3 method for class 'gnlsStruct'
residuals(object, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>gnlsStruct</code> ", representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects, and attributes specifying the underlying nonlinear model and the response variable.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a vector with the residuals for the nonlinear model represented by `object`.

**Note**

This method function is primarily used inside `gnls` and `residuals.gnls`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`gnls`, `residuals.gnls`, `fitted.gnlsStruct`

---

<code>residuals.lme</code>	<i>Extract lme Residuals</i>
----------------------------	------------------------------

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted levels at that level from the response vector (and dividing by the estimated within-group standard error, if `type="pearson"`). The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
## S3 method for class 'lme'
residuals(object, level = 0,
          type = c("response", "pearson", "normalized"), asList = FALSE, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population residuals. Defaults to the highest or innermost level of grouping.
<code>type</code>	an optional character string specifying the type of residuals to be used. If " <code>response</code> ", as by default, the “raw” residuals (observed - fitted) are used; else, if " <code>pearson</code> ", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if " <code>normalized</code> ", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided.
<code>asList</code>	an optional logical value. If <code>TRUE</code> and a single value is given in <code>level</code> , the returned object is a list with the residuals split by groups; else the returned value is either a vector or a data frame, according to the length of <code>level</code> . Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

if a single level of grouping is specified in `level`, the returned value is either a list with the residuals split by groups (`asList = TRUE`) or a vector with the residuals (`asList = FALSE`); else, when multiple grouping levels are specified in `level`, the returned object is a data frame with columns given by the residuals at different levels and the grouping factors. For a vector or data frame result the `naresid` method is applied.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`lme`, `fitted.lme`

**Examples**

```
fml <- lme(distance ~ age + Sex, data = Orthodont, random = ~ 1)
head(residuals(fml, level = 0:1))
summary(residuals(fml) /
        residuals(fml, type = "p")) # constant scaling factor 1.432
```

---

```
residuals.lmeStruct
```

*Calculate lmeStruct Residuals*

---

**Description**

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the population fitted values (based only on the fixed effects estimates) and the estimated contributions of the random effects to the fitted values at grouping levels less or equal to  $i$ .

**Usage**

```
## S3 method for class 'lmeStruct'
residuals(object, level, conLin, lmeFit, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lmeStruct</code> ", representing a list of linear mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
<code>level</code>	an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
<code>conLin</code>	an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying <code>lme</code> model. Defaults to <code>attr(object, "conLin")</code> .

lmeFit	an optional list with components <code>beta</code> and <code>b</code> containing respectively the fixed effects estimates and the random effects estimates to be used to calculate the residuals. Defaults to <code>attr(object, "lmeFit")</code> .
...	some methods for this generic accept optional arguments.

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the `lme` function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`lme`, `residuals.lme`, `fitted.lmeStruct`

---

residuals.lmList	<i>Extract lmList Residuals</i>
------------------	---------------------------------

---

**Description**

The residuals are extracted from each `lm` component of `object` and arranged into a list with as many components as `object`, or combined into a single vector.

**Usage**

```
## S3 method for class 'lmList'
residuals(object, type, subset, asList, ...)
```

**Arguments**

object	an object inheriting from class <code>"lmList"</code> , representing a list of <code>lm</code> objects with a common model.
subset	an optional character or integer vector naming the <code>lm</code> components of <code>object</code> from which the residuals are to be extracted. Default is <code>NULL</code> , in which case all components are used.
type	an optional character string specifying the type of residuals to be extracted. Options include <code>"response"</code> for the "raw" residuals (observed - fitted), <code>"pearson"</code> for the standardized residuals (raw residuals divided by the estimated residual standard error) using different standard errors for each <code>lm</code> fit, and <code>"pooled.pearson"</code> for the standardized residuals using a pooled estimate of the residual standard error. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"response"</code> .

asList	an optional logical value. If <code>TRUE</code> , the returned object is a list with the residuals split by groups; else the returned value is a vector. Defaults to <code>FALSE</code> .
...	some methods for this generic require additional arguments. None are used in this method.

### Value

a list with components given by the residuals of each `lm` component of `object`, or a vector with the residuals for all `lm` components of `object`.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[lmList](#), [fitted.lmList](#)

### Examples

```
fml <- lmList(distance ~ age | Subject, Orthodont)
residuals(fml)
```

---

```
residuals.nlmeStruct
```

*Calculate nlmeStruct Residuals*

---

### Description

The residuals at level  $i$  are obtained by subtracting the fitted values at that level from the response vector. The fitted values at level  $i$  are obtained by adding together the contributions from the estimated fixed effects and the estimated random effects at levels less or equal to  $i$  and evaluating the model function at the resulting estimated parameters.

### Usage

```
## S3 method for class 'nlmeStruct'
residuals(object, level, conLin, ...)
```

### Arguments

object	an object inheriting from class " <a href="#">nlmeStruct</a> ", representing a list of mixed-effects model components, such as <code>reStruct</code> , <code>corStruct</code> , and <code>varFunc</code> objects.
level	an optional integer vector giving the level(s) of grouping to be used in extracting the residuals from <code>object</code> . Level values increase from outermost to innermost grouping, with level zero corresponding to the population fitted values. Defaults to the highest or innermost level of grouping.
conLin	an optional condensed linear model object, consisting of a list with components " <code>Xy</code> ", corresponding to a regression matrix ( $X$ ) combined with a response vector ( $y$ ), and " <code>logLik</code> ", corresponding to the log-likelihood of the underlying <code>nlme</code> model. Defaults to <code>attr(object, "conLin")</code> .
...	optional arguments to the residuals generic. Not used.

**Value**

if a single level of grouping is specified in `level`, the returned value is a vector with the residuals at the desired level; else, when multiple grouping levels are specified in `level`, the returned object is a matrix with columns given by the residuals at different levels.

**Note**

This method function is primarily used within the `nlme` function.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

reStruct

*Random Effects Structure*

---

**Description**

This function is a constructor for the `reStruct` class, representing a random effects structure and consisting of a list of `pdMat` objects, plus a `settings` attribute containing information for the optimization algorithm used to fit the associated mixed-effects model.

**Usage**

```
reStruct(object, pdClass, REML, data)
## S3 method for class 'reStruct'
print(x, sigma, reEstimates, verbose, ...)
```

**Arguments**

`object` any of the following: (i) a one-sided formula of the form `~x1+...+xn | g1/.../gm`, with `x1+...+xn` specifying the model for the random effects and `g1/.../gm` the grouping structure (`m` may be equal to 1, in which case no `/` is required). The random effects formula will be repeated for all levels of grouping, in the case of multiple levels of grouping; (ii) a list of one-sided formulas of the form `~x1+...+xn | g`, with possibly different random effects models for each grouping level. The order of nesting will be assumed the same as the order of the elements in the list; (iii) a one-sided formula of the form `~x1+...+xn`, or a `pdMat` object with a formula (i.e. a non-NULL value for `formula(object)`), or a list of such formulas or `pdMat` objects. In this case, the grouping structure formula will be derived from the data used to fit the mixed-effects model, which should inherit from

	class <code>groupedData</code> ; (iv) a named list of formulas or <code>pdMat</code> objects as in (iii), with the grouping factors as names. The order of nesting will be assumed the same as the order of the elements in the list; (v) an <code>reStruct</code> object.
<code>pdClass</code>	an optional character string with the name of the <code>pdMat</code> class to be used for the formulas in <code>object</code> . Defaults to <code>"pdSymm"</code> which corresponds to a general positive-definite matrix.
<code>REML</code>	an optional logical value. If <code>TRUE</code> , the associated mixed-effects model will be fitted using restricted maximum likelihood; else, if <code>FALSE</code> , maximum likelihood will be used. Defaults to <code>FALSE</code> .
<code>data</code>	an optional data frame in which to evaluate the variables used in the random effects formulas in <code>object</code> . It is used to obtain the levels for factors, which affect the dimensions and the row/column names of the underlying <code>pdMat</code> objects. If <code>NULL</code> , no attempt is made to obtain information on factors appearing in the formulas. Defaults to the parent frame from which the function was called.
<code>x</code>	an object inheriting from class <code>reStruct</code> to be printed.
<code>sigma</code>	an optional numeric value used as a multiplier for the square-root factors of the <code>pdMat</code> components (usually the estimated within-group standard deviation from a mixed-effects model). Defaults to 1.
<code>reEstimates</code>	an optional list with the random effects estimates for each level of grouping. Only used when <code>verbose = TRUE</code> .
<code>verbose</code>	an optional logical value determining if the random effects estimates should be printed. Defaults to <code>FALSE</code> .
<code>...</code>	Optional arguments can be given to other methods for this generic. None are used in this method.

### Value

an object inheriting from class `reStruct`, representing a random effects structure.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

`groupedData`, `lme`, `pdMat`, `solve.reStruct`, `summary.reStruct`,  
`update.reStruct`

### Examples

```
rs1 <- reStruct(list(Dog = ~day, Side = ~1), data = Pixel)
rs1
```

simulate.lme

*Simulate Results from lme Models***Description**

The model `object` is fit to the data. Using the fitted values of the parameters, `nsim` new data vectors from this model are simulated. Both `m1` and `m2` are fit by maximum likelihood (ML) and/or by restricted maximum likelihood (REML) to each of the simulated data vectors.

**Usage**

```
## S3 method for class 'lme'
simulate(object, nsim, seed, m2, method, niterEM, useGen, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model, or a list containing an <code>lme</code> model specification. If given as a list, it should contain components <code>fixed</code> , <code>data</code> , and <code>random</code> with values suitable for a call to <code>lme</code> . This argument defines the null model.
<code>m2</code>	an <code>lme</code> object, or a list, like <code>m1</code> containing a second <code>lme</code> model specification. This argument defines the alternative model. If given as a list, only those parts of the specification that change between model <code>m1</code> and <code>m2</code> need to be specified.
<code>seed</code>	an optional integer that is passed to <code>set.seed</code> . Defaults to a random integer.
<code>method</code>	an optional character array. If it includes "REML" the models are fit by maximizing the restricted log-likelihood. If it includes "ML" the log-likelihood is maximized. Defaults to <code>c("REML", "ML")</code> , in which case both methods are used.
<code>nsim</code>	an optional positive integer specifying the number of simulations to perform. Defaults to <b>1</b> . <b>This has changed. Previously the default was 1000.</b>
<code>niterEM</code>	an optional integer vector of length 2 giving the number of iterations of the EM algorithm to apply when fitting the <code>m1</code> and <code>m2</code> to each simulated set of data. Defaults to <code>c(40, 200)</code> .
<code>useGen</code>	an optional logical value. If <code>TRUE</code> , numerical derivatives are used to obtain the gradient and the Hessian of the log-likelihood in the optimization algorithm in the <code>ms</code> function. If <code>FALSE</code> , the default algorithm in <code>ms</code> for functions that do not incorporate gradient and Hessian attributes is used. Default depends on the " <code>pdMat</code> " classes used in <code>m1</code> and <code>m2</code> : if both are standard classes (see <code>pdClasses</code> ) then defaults to <code>TRUE</code> , otherwise defaults to <code>FALSE</code> .
<code>...</code>	optional additional arguments. None are used.

**Value**

an object of class `simulate.lme` with components `null` and `alt`. Each of these has components `ML` and/or `REML` which are matrices. An attribute called `Random.seed` contains the seed that was used for the random number generator.

**Author(s)**

```

---

`solve.pdMat`

*Calculate Inverse of a Positive-Definite Matrix*

---

## Description

The positive-definite matrix represented by `a` is inverted and assigned to `a`.

## Usage

```
## S3 method for class 'pdMat'
solve(a, b, ...)
```

## Arguments

<code>a</code>	an object inheriting from class " <a href="#">pdMat</a> ", representing a positive definite matrix.
<code>b</code>	this argument is only included for consistency with the generic function and is not used in this method function.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

a `pdMat` object similar to `a`, but with coefficients corresponding to the inverse of the positive-definite matrix represented by `a`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

**Description**

Solve is applied to each `pdMat` component of `a`, which results in inverting the positive-definite matrices they represent.

**Usage**

```
## S3 method for class 'reStruct'
solve(a, b, ...)
```

**Arguments**

<code>a</code>	an object inheriting from class " <code>reStruct</code> ", representing a random effects structure and consisting of a list of <code>pdMat</code> objects.
<code>b</code>	this argument is only included for consistency with the generic function and is not used in this method function.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an `reStruct` object similar to `a`, but with the `pdMat` components representing the inverses of the matrices represented by the components of `a`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[solve.pdMat](#), [reStruct](#)

**Examples**

```
rs1 <- reStruct(list(A = pdSymm(diag(1:3), form = ~Score),
  B = pdDiag(2 * diag(4), form = ~Educ)))
solve(rs1)
```

Soybean

*Growth of soybean plants***Description**

The Soybean data frame has 412 rows and 5 columns.

**Format**

This data frame contains the following columns:

**Plot** a factor giving a unique identifier for each plot.

**Variety** a factor indicating the variety; Forrest (F) or Plant Introduction \#416937 (P).

**Year** a factor indicating the year the plot was planted.

**Time** a numeric vector giving the time the sample was taken (days after planting).

**weight** a numeric vector giving the average leaf weight per plant (g).

**Details**

These data are described in Davidian and Giltinan (1995, 1.1.3, p.7) as “Data from an experiment to compare growth patterns of two genotypes of soybeans: Plant Introduction \#416937 (P), an experimental strain, and Forrest (F), a commercial variety.”

**Source**

Davidian, M. and Giltinan, D. M. (1995), *Nonlinear Models for Repeated Measurement Data*, Chapman and Hall, London.

**Examples**

```
summary(fml <- nlsList(SSlogis, data = Soybean))
```

splitFormula

*Split a Formula***Description**

Splits the right hand side of `form` into a list of subformulas according to the presence of `sep`. The left hand side of `form`, if present, will be ignored. The length of the returned list will be equal to the number of occurrences of `sep` in `form` plus one.

**Usage**

```
splitFormula(form, sep)
```

**Arguments**

<code>form</code>	a formula object.
<code>sep</code>	an optional character string specifying the separator to be used for splitting the formula. Defaults to <code>" / "</code> .

**Value**

a list of formulas, corresponding to the split of `form` according to `sep`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

**Examples**

```
splitFormula(~ g1/g2/g3)
```

---

Spruce

*Growth of Spruce Trees*

---

**Description**

The `Spruce` data frame has 1027 rows and 4 columns.

**Format**

This data frame contains the following columns:

**tree** a factor giving a unique identifier for each tree.

**days** a numeric vector giving the number of days since the beginning of the experiment.

**logSize** a numeric vector giving the logarithm of an estimate of the volume of the tree trunk.

**plot** a factor identifying the plot in which the tree was grown.

**Details**

Diggle, Liang, and Zeger (1994, Example 1.3, page 5) describe data on the growth of spruce trees that have been exposed to an ozone-rich atmosphere or to a normal atmosphere.

---

`summary.corStruct` *Summarize a corStruct Object*

---

### Description

This method function prepares `object` to be printed using the `print.summary` method, by changing its class and adding a `structName` attribute to it.

### Usage

```
## S3 method for class 'corStruct'
summary(object, structName, ...)
```

### Arguments

<code>object</code>	an object inheriting from class " <code>corStruct</code> ", representing a correlation structure.
<code>structName</code>	an optional character string defining the type of correlation structure associated with <code>object</code> , to be used in the <code>print.summary</code> method. Defaults to <code>class(object)[1]</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

an object identical to `object`, but with its class changed to `summary.corStruct` and an additional attribute `structName`. The returned value inherits from the same classes as `object`.

### Author(s)

José Pinheiro and Douglas Bates

### See Also

`corClasses`, `corNatural`, `Initialize.corStruct`, `summary`

### Examples

```
cs1 <- corAR1(0.2)
summary(cs1)
```

---

summary.gls      *Summarize a gls Object*

---

**Description**

Additional information about the linear model fit represented by `object` is extracted and included as components of `object`.

**Usage**

```
## S3 method for class 'gls'
summary(object, verbose, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">gls</a> ", representing a generalized least squares fitted linear model.
<code>verbose</code>	an optional logical value used to control the amount of output when the object is printed. Defaults to FALSE.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object inheriting from class `summary.gls` with all components included in `object` (see [glsObject](#) for a full description of the components) plus the following components:

<code>corBeta</code>	approximate correlation matrix for the coefficients estimates
<code>tTable</code>	a data frame with columns <code>Value</code> , <code>Std. Error</code> , <code>t-value</code> , and <code>p-value</code> representing respectively the coefficients estimates, their approximate standard errors, the ratios between the estimates and their standard errors, and the associated p-value under a <i>t</i> approximation. Rows correspond to the different coefficients.
<code>residuals</code>	if more than five observations are used in the <code>gls</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the residuals distribution; else the residuals.
<code>AIC</code>	the Akaike Information Criterion corresponding to <code>object</code> .
<code>BIC</code>	the Bayesian Information Criterion corresponding to <code>object</code> .

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

[AIC](#), [BIC](#), [gls](#), [summary](#)

**Examples**

```
fml <- gls(follicles ~ sin(2*pi*Time) + cos(2*pi*Time), Ovary,
          correlation = corAR1(form = ~ 1 | Mare))
summary(fml)
```

summary.lme

*Summarize an lme Object***Description**

Additional information about the linear mixed-effects fit represented by `object` is extracted and included as components of `object`. The returned object is suitable for printing with the `print.summary.lme` method.

**Usage**

```
## S3 method for class 'lme'
summary(object, adjustSigma, verbose, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>lme</code> ", representing a fitted linear mixed-effects model.
<code>adjustSigma</code>	an optional logical value. If <code>TRUE</code> and the estimation method used to obtain <code>object</code> was maximum likelihood, the residual standard error is multiplied by $\sqrt{n_{obs}/(n_{obs} - n_{par})}$ , converting it to a REML-like estimate. This argument is only used when a single fitted object is passed to the function. Default is <code>TRUE</code> .
<code>verbose</code>	an optional logical value used to control the amount of output in the <code>print.summary.lme</code> method. Defaults to <code>FALSE</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object inheriting from class `summary.lme` with all components included in `object` (see `lmeObject` for a full description of the components) plus the following components:

<code>corFixed</code>	approximate correlation matrix for the fixed effects estimates
<code>tTable</code>	a data frame with columns <code>Value</code> , <code>Std. Error</code> , <code>DF</code> , <code>t-value</code> , and <code>p-value</code> representing respectively the fixed effects estimates, their approximate standard errors, the denominator degrees of freedom, the ratios between the estimates and their standard errors, and the associated p-value from a t distribution. Rows correspond to the different fixed effects.
<code>residuals</code>	if more than five observations are used in the <code>lme</code> fit, a vector with the minimum, first quartile, median, third quartile, and maximum of the innermost grouping level residuals distribution; else the innermost grouping level residuals.
<code>AIC</code>	the Akaike Information Criterion corresponding to <code>object</code> .
<code>BIC</code>	the Bayesian Information Criterion corresponding to <code>object</code> .

---

summary.lmList	<i>Summarize an lmList Object</i>
----------------	-----------------------------------

---

Description

The `summary.lm` method is applied to each `lm` component of `object` to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the `print.summary.lmList` method.

Usage

```
## S3 method for class 'lmList'
summary(object, pool, ...)
```

Arguments

- |                     |  |
|---------------------|--|
| <code>object</code> | an object inheriting from class " <a href="#">lmList</a> ", representing a list of <code>lm</code> fitted objects.   |
| <code>pool</code>   | an optional logical value indicating whether a pooled estimate of the residual standard error should be used. Default is <code>attr(object, "pool")</code> . |
| <code>...</code>    | some methods for this generic require additional arguments. None are used in this method.  |

Value

a list with summary statistics obtained by applying `summary.lm` to the elements of `object`, inheriting from class `summary.lmList`. The components of value are:

- |                           |  |
|---------------------------|--|
| <code>call</code>         | a list containing an image of the <code>lmList</code> call that produced <code>object</code> .   |
| <code>coefficients</code> | a three dimensional array with summary information on the <code>lm</code> coefficients. The first dimension corresponds to the names of the <code>object</code> components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names. |
| <code>correlation</code>  | a three dimensional array with the correlations between the individual <code>lm</code> coefficient estimates. The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by <code>lm</code> component.                  |

<code>cov.unscaled</code>	a three dimensional array with the unscaled variances/covariances for the individual <code>lm</code> coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by <code>lm</code> component.
<code>df</code>	an array with the number of degrees of freedom for the model and for residuals, for each <code>lm</code> component.
<code>df.residual</code>	the total number of degrees of freedom for residuals, corresponding to the sum of residuals <code>df</code> of all <code>lm</code> components.
<code>fstatistics</code>	an array with the F test statistics and corresponding degrees of freedom, for each <code>lm</code> component.
<code>pool</code>	the value of the <code>pool</code> argument to the function.
<code>r.squared</code>	a vector with the multiple R-squared statistics for each <code>lm</code> component.
<code>residuals</code>	a list with components given by the residuals from individual <code>lm</code> fits.
<code>RSE</code>	the pooled estimate of the residual standard error.
<code>sigma</code>	a vector with the residual standard error estimates for the individual <code>lm</code> fits.
<code>terms</code>	the terms object used in fitting the individual <code>lm</code> components.

```
summary.modelStruct
```

*Summarize a modelStruct Object*

---

**Description**

This method function applies `summary` to each element of `object`.

**Usage**

```
## S3 method for class 'modelStruct'
summary(object, ...)
```

**Arguments**

object	an object inheriting from class "modelStruct", representing a list of model components, such as reStruct, corStruct and varFunc objects.
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a list with elements given by the summarized components of object. The returned value is of class summary.modelStruct, also inheriting from the same classes as object.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

reStruct, summary

**Examples**

```
lms1 <- lmeStruct(reStruct = reStruct(pdDiag(diag(2), ~age)),
  corStruct = corAR1(0.3))
summary(lms1)
```

---

summary.nlsList	<i>Summarize an nlsList Object</i>
-----------------	------------------------------------

---

**Description**

The summary function is applied to each nls component of object to produce summary information on the individual fits, which is organized into a list of summary statistics. The returned object is suitable for printing with the print.summary.nlsList method.

**Usage**

```
## S3 method for class 'nlsList'
summary(object, ...)
```

**Arguments**

object	an object inheriting from class "nlsList", representing a list of nls fitted objects.
...	optional arguments to the summary.lmList method. One such optional argument is pool, a logical value indicating whether a pooled estimate of the residual standard error should be used. Default is attr(object, "pool").

**Value**

a list with summary statistics obtained by applying `summary` to the elements of `object`, inheriting from class `summary.nlsList`. The components of `value` are:

<code>call</code>	a list containing an image of the <code>nlsList</code> call that produced <code>object</code> .
<code>parameters</code>	a three dimensional array with summary information on the <code>nls</code> coefficients. The first dimension corresponds to the names of the <code>object</code> components, the second dimension is given by "Value", "Std. Error", "t value", and "Pr(> t )", corresponding, respectively, to the coefficient estimates and their associated standard errors, t-values, and p-values. The third dimension is given by the coefficients names.
<code>correlation</code>	a three dimensional array with the correlations between the individual <code>nls</code> coefficient estimates. The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the correlations between that coefficient and the remaining coefficients, by <code>nls</code> component.
<code>cov.unscaled</code>	a three dimensional array with the unscaled variances/covariances for the individual <code>lm</code> coefficient estimates (giving the estimated variance/covariance for the coefficients, when multiplied by the estimated residual errors). The first dimension corresponds to the names of the <code>object</code> components. The third dimension is given by the coefficients names. For each coefficient, the rows of the associated array give the unscaled covariances between that coefficient and the remaining coefficients, by <code>nls</code> component.
<code>df</code>	an array with the number of degrees of freedom for the model and for residuals, for each <code>nls</code> component.
<code>df.residual</code>	the total number of degrees of freedom for residuals, corresponding to the sum of residuals <code>df</code> of all <code>nls</code> components.
<code>pool</code>	the value of the <code>pool</code> argument to the function.
<code>RSE</code>	the pooled estimate of the residual standard error.
<code>sigma</code>	a vector with the residual standard error estimates for the individual <code>lm</code> fits.

summary.pdMat

*Summarize a pdMat Object***Description**

Attributes `structName` and `noCorrelation`, with the values of the corresponding arguments to the method function, are appended to `object` and its class is changed to `summary.pdMat`.

**Usage**

```
## S3 method for class 'pdMat'
summary(object, structName, noCorrelation, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>pdMat</code> ", representing a positive definite matrix.
<code>structName</code>	an optional character string with a description of the <code>pdMat</code> class. Default depends on the method function: "Blocked" for <code>pdBlocked</code> , "Compound Symmetry" for <code>pdCompSymm</code> , "Diagonal" for <code>pdDiag</code> , "Multiple of an Identity" for <code>pdIdent</code> , "General Positive-Definite, Natural Parametrization" for <code>pdNatural</code> , "General Positive-Definite" for <code>pdSymm</code> , and <code>data.class(object)</code> for <code>pdMat</code> .
<code>noCorrelation</code>	an optional logical value indicating whether correlations are to be printed in <code>print.summary.pdMat</code> . Default depends on the method function: FALSE for <code>pdDiag</code> and <code>pdIdent</code> , and TRUE for all other classes.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

an object similar to `object`, with additional attributes `structName` and `noCorrelation`, inheriting from class `summary.pdMat`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**See Also**

`print.summary.pdMat`, `pdMat`

**Examples**

```
summary(pdSymm(diag(4)))
```

---

summary.varFunc	<i>Summarize varFunc Object</i>
-----------------	---------------------------------

---

## Description

A `structName` attribute, with the value of corresponding argument, is appended to `object` and its class is changed to `summary.varFunc`.

## Usage

```
## S3 method for class 'varFunc'
summary(object, structName, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>varFunc</code> ", representing a variance function structure.
<code>structName</code>	an optional character string with a description of the <code>varFunc</code> class. Default depends on the method function: "Combination of variance functions" for <code>varComb</code> , "Constant plus power of covariate" for <code>varConstPower</code> , "Exponential of variance covariate" for <code>varExp</code> , "Different standard deviations per stratum" for <code>varIdent</code> , "Power of variance covariate" for <code>varPower</code> , and <code>data.class(object)</code> for <code>varFunc</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

## Value

an object similar to `object`, with an additional attribute `structName`, inheriting from class `summary.varFunc`.

## Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

update.modelStruct *Update a modelStruct Object*

---

### Description

This method function updates each element of `object`, allowing the access to data.

### Usage

```
## S3 method for class 'modelStruct'
update(object, data, ...)
```

### Arguments

<code>object</code>	an object inheriting from class "modelStruct", representing a list of model components, such as <code>corStruct</code> and <code>varFunc</code> objects.
<code>data</code>	a data frame in which to evaluate the variables needed for updating the elements of <code>object</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

an object similar to `object` (same class, length, and names), but with updated elements.

### Note

This method function is primarily used within model fitting functions, such as `lme` and `gls`, that allow model components such as variance functions.

### Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

### See Also

[reStruct](#)

---

update.varFunc *Update varFunc Object*

---

### Description

If the `formula(object)` includes a "." term, representing a fitted object, the variance covariate needs to be updated upon completion of an optimization cycle (in which the variance function weights are kept fixed). This method function allows a reevaluation of the variance covariate using the current fitted object and, optionally, other variables in the original data.

Usage

```
## S3 method for class 'varFunc'  
update(object, data, ...)
```

Arguments

- object      an object inheriting from class "**varFunc**", representing a variance function structure.
- data        a list with a component named "." with the current version of the fitted object (from which fitted values, coefficients, and residuals can be extracted) and, if necessary, other variables used to evaluate the variance covariate(s).
- ...        some methods for this generic require additional arguments. None are used in this method.

Value

if `formula(object)` includes a "." term, an `varFunc` object similar to `object`, but with the variance covariate reevaluated at the current fitted object value; else `object` is returned unchanged.

Author(s)

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```
needUpdate, covariate<-.varFunc
```

---

varClasses	<i>Variance Function Classes</i>
------------	----------------------------------

---

Description

Standard classes of variance function structures (`varFunc`) available in the `nlme` package. Co-variates included in the variance function, denoted by variance covariates, may involve functions of the fitted model object, such as the fitted values and the residuals. Different coefficients may be assigned to the levels of a classification factor.

Value

Available standard classes:

- `varExp`      exponential of a variance covariate.
- `varPower`    power of a variance covariate.
- `varConstPower`      constant plus power of a variance covariate.
- `varIdent`    constant variance(s), generally used to allow different variances according to the levels of a classification factor.
- `varFixed`    fixed weights, determined by a variance covariate.
- `varComb`    combination of variance functions.

**Note**

Users may define their own `varFunc` classes by specifying a constructor function and, at a minimum, methods for the functions `coef`, `coef<-`, and `initialize`. For examples of these functions, see the methods for class `varPower`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

`varComb`

*Combination of Variance Functions*

---

**Description**

This function is a constructor for the `varComb` class, representing a combination of variance functions. The corresponding variance function is equal to the product of the variance functions of the `varFunc` objects listed in . . . .

**Usage**

```
varComb(...)
```

**Arguments**

. . .                      objects inheriting from class `varFunc` representing variance function structures.

**Value**

a `varComb` object representing a combination of variance functions, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

**See Also**

`varClasses`, `varWeights.varComb`, `coef.varComb`

## Examples

```
vfl <- varComb(varIdent(form = ~1|Sex), varPower())
```

---

varConstPower

*Constant Plus Power Variance Function*

---

## Description

This function is a constructor for the `varConstPower` class, representing a constant plus power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the constant plus power variance function is defined as  $\sigma^2(v) = (\theta_1 + |v|_2^\theta)^2$ , where  $\theta_1, \theta_2$  are the variance function coefficients. When a grouping factor is present, different  $\theta_1, \theta_2$  are used for each factor level.

## Usage

```
varConstPower(const, power, form, fixed)
```

## Arguments

- `const, power` optional numeric vectors, or lists of numeric values, with, respectively, the coefficients for the constant and the power terms. Both arguments must have length one, unless a grouping factor is specified in `form`. If either argument has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in `form`. If a grouping factor is present in `form` and the argument has length one, its value will be assigned to all grouping levels. Only positive values are allowed for `const`. Default is `numeric(0)`, which results in a vector of zeros of appropriate length being assigned to the coefficients when `object` is initialized (corresponding to constant variance equal to one).
- `form` an optional one-sided formula of the form `~ v`, or `~ v | g`, specifying a variance covariate `v` and, optionally, a grouping factor `g` for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using `"."`, representing a fitted model object from which fitted values (`fitted(.)`) and residuals (`resid(.)`) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in `form`, a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the `*` operator, as in `~ v | g1 * g2 * g3`. In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.
- `fixed` an optional list with components `const` and/or `power`, consisting of numeric vectors, or lists of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, the components of `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

**Value**

a `varConstPower` object representing a constant plus power variance function structure, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**References**

Pinheiro, J.C., and Bates, D.M. (2000) "Mixed-Effects Models in S and S-PLUS", Springer.

```
vfl <- varConstPower(1.2, 0.2, form = ~age|Sex)
```

---

VarCorr

---

*Extract variance and correlation components*

---

**Description**

This function calculates the estimated variances, standard deviations, and correlations between the random-effects terms in a linear mixed-effects model, of class "`lme`", or a nonlinear mixed-effects model, of class "`nlme`". The within-group error variance and standard deviation are also calculated.

**Usage**

```
VarCorr(x, sigma, rdig)
```

**Arguments**

<code>x</code>	a fitted model object, usually an object inheriting from class " <code>lme</code> ".
<code>sigma</code>	an optional numeric value used as a multiplier for the standard deviations. Default is 1.
<code>rdig</code>	an optional integer value specifying the number of digits used to represent correlation estimates. Default is 3.

**Value**

a matrix with the estimated variances, standard deviations, and correlations for the random effects. The first two columns, named `Variance` and `StdDev`, give, respectively, the variance and the standard deviations. If there are correlation components in the random effects model, the third column, named `Corr`, and the remaining unnamed columns give the estimated correlations among random effects within the same level of grouping. The within-group error variance and standard deviation are included as the last row in the matrix.

varExp

---

*Exponential Variance Function*

---

**Description**

This function is a constructor for the `varExp` class, representing an exponential variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the exponential variance function is defined as  $\sigma^2(v) = \exp(2\theta v)$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varExp(value, form, fixed)
```

**Arguments**

value	an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in <code>form</code> . If <code>value</code> has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and <code>value</code> has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).
form	an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting

factor is used to group the observations. Defaults to `~ fitted(.)` representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.

`fixed` an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in `form`, `fixed` must have names identifying which coefficients are to be fixed. Coefficients included in `fixed` are not allowed to vary during the optimization of an objective function. Defaults to `NULL`, corresponding to no fixed coefficients.

Value

a `varExp` object representing an exponential variance function structure, also inheriting from class `varFunc`.

```

---

varFixed	<i>Fixed Variance Function</i>
----------	--------------------------------

---

Description

This function is a constructor for the `varFixed` class, representing a variance function with fixed variances. Letting  $v$  denote the variance covariate defined in `value`, the variance function  $\sigma^2(v)$  for this class is  $\sigma^2(v) = |v|$ . The variance covariate  $v$  is evaluated once at initialization and remains fixed thereafter. No coefficients are required to represent this variance function.

Usage

```
varFixed(value)
```

Arguments

`value` a one-sided formula of the form `~ v` specifying a variance covariate `v`. Grouping factors are ignored.

**Value**

a `varFixed` object representing a fixed variance function structure, also inheriting from class `varFunc`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

```

---

varFunc

*Variance Function Structure*

---

**Description**

If `object` is a one-sided formula, it is used as the argument to `varFixed` and the resulting object is returned. Else, if `object` inherits from class `varFunc`, it is returned unchanged.

**Usage**

```
varFunc(object)
```

**Arguments**

`object` either an one-sided formula specifying a variance covariate, or an object inheriting from class `varFunc`, representing a variance function structure.

**Value**

an object from class `varFunc`, representing a variance function structure.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
vf1 <- varFunc(~age)
```

varIdent

*Constant Variance Function***Description**

This function is a constructor for the `varIdent` class, representing a constant variance function structure. If no grouping factor is present in `form`, the variance function is constant and equal to one, and no coefficients required to represent it. When `form` includes a grouping factor with  $M > 1$  levels, the variance function allows  $M$  different variances, one for each level of the factor. For identifiability reasons, the coefficients of the variance function represent the ratios between the variances and a reference variance (corresponding to a reference group level). Therefore, only  $M - 1$  coefficients are needed to represent the variance function. By default, if the elements in `value` are unnamed, the first group level is taken as the reference level.

**Usage**

```
varIdent(value, form, fixed)
```

**Arguments**

- |                    |   |
|--------------------|---|
| <code>value</code> | an optional numeric vector, or list of numeric values, with the variance function coefficients. If no grouping factor is present in <code>form</code> , this argument is ignored, as the resulting variance function contains no coefficients. If <code>value</code> has length one, its value is repeated for all coefficients in the variance function. If <code>value</code> has length greater than one, it must have length equal to the number of grouping levels minus one and names which identify its elements to the levels of the grouping factor. Only positive values are allowed for this argument. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when <code>object</code> is initialized (corresponding to constant variance equal to one). |
| <code>form</code>  | an optional one-sided formula of the form <code>~ v</code> , or <code>~ v   g</code> , specifying a variance covariate <code>v</code> and, optionally, a grouping factor <code>g</code> for the coefficients. The variance covariate is ignored in this variance function. When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels less one reference level (see description section below). Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in <code>~ v   g1 * g2 * g3</code> . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to <code>~ 1</code> .  |
| <code>fixed</code> | an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. It must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.  |

---

Variogram	<i>Calculate Semi-variogram</i>
-----------	---------------------------------

---

**Description**

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include `default`, `gls` and `lme`. See the appropriate method documentation for a description of the arguments.

**Usage**

```
Variogram(object, distance, ...)
```

**Arguments**

<code>object</code>	a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.
<code>distance</code>	a numeric vector with the pairwise distances corresponding to the elements of <code>object</code> . The order of the elements in <code>distance</code> must correspond to the pairs $(1, 2)$ , $(1, 3)$ , $\dots$ , $(n-1, n)$ , with $n$ representing the length of <code>object</code> , and must have length $n(n-1)/2$ .
<code>...</code>	some methods for this generic function require additional arguments.

**Value**

will depend on the method function used; see the appropriate documentation.

`Variogram.corExp`     *Calculate Semi-variogram for a corExp Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Exponential correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corExp'
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>corExp</code> ", representing an exponential spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

**Author(s)**

```

---

Variogram.corGaus    *Calculate Semi-variogram for a corGaus Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Gaussian correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corGaus'
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>corGaus</code> ", representing an Gaussian spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

---

`Variogram.corLin`     *Calculate Semi-variogram for a corLin Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Linear correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corLin'
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <code>corLin</code> ", representing an Linear spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

---

Variogram.corRatio *Calculate Semi-variogram for a corRatio Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the Rational Quadratic correlation model, using the estimated coefficients corresponding to `object`, at the distances defined by `distance`.

**Usage**

```
## S3 method for class 'corRatio'
Variogram(object, distance, sig2, length.out, ...)
```

**Arguments**

<code>object</code>	an object inheriting from class " <a href="#">corRatio</a> ", representing an Rational Quadratic spatial correlation structure.
<code>distance</code>	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to <code>NULL</code> , in which case a sequence of length <code>length.out</code> between the minimum and maximum values of <code>getCovariate(object)</code> is used.
<code>sig2</code>	an optional numeric value representing the process variance. Defaults to 1.
<code>length.out</code>	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when <code>distance = NULL</code> . Defaults to 50.
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

---

Variogram.corSpatial

*Calculate Semi-variogram for a corSpatial Object*

---

**Description**

This method function calculates the semi-variogram values corresponding to the model defined in FUN, using the estimated coefficients corresponding to object, at the distances defined by distance.

**Usage**

```
## S3 method for class 'corSpatial'
Variogram(object, distance, sig2, length.out, FUN, ...)
```

**Arguments**

object	an object inheriting from class " <a href="#">corSpatial</a> ", representing spatial correlation structure.
distance	an optional numeric vector with the distances at which the semi-variogram is to be calculated. Defaults to NULL, in which case a sequence of length length.out between the minimum and maximum values of getCovariate(object) is used.
sig2	an optional numeric value representing the process variance. Defaults to 1.
length.out	an optional integer specifying the length of the sequence of distances to be used for calculating the semi-variogram, when distance = NULL. Defaults to 50.
FUN	a function of two arguments, the distance and the range corresponding to object, specifying the semi-variogram model.
...	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns variog and dist representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class Variogram.

```

---

Variogram.default    *Calculate Semi-variogram*

---

**Description**

This method function calculates the semi-variogram for an arbitrary vector `object`, according to the distances in `distance`. For each pair of elements  $x, y$  in `object`, the corresponding semi-variogram is  $(x - y)^2/2$ . The semi-variogram is useful for identifying and modeling spatial correlation structures in observations with constant expectation and constant variance.

**Usage**

```
## Default S3 method:
Variogram(object, distance, ...)
```

**Arguments**

<code>object</code>	a numeric vector with the values to be used for calculating the semi-variogram, usually a residual vector from a fitted model.
<code>distance</code>	a numeric vector with the pairwise distances corresponding to the elements of <code>object</code> . The order of the elements in <code>distance</code> must correspond to the pairs $(1, 2)$ , $(1, 3)$ , $\dots$ , $(n-1, n)$ , with $n$ representing the length of <code>object</code> , and must have length $n(n-1)/2$ .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. The returned value inherits from class `Variogram`.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

## Examples

```
## Not run:
fm1 <- lm(follicles ~ sin(2 * pi * Time) + cos(2 * pi * Time), Ovary,
         subset = Mare == 1)
Variogram(resid(fm1), dist(1:29))[1:10,]

## End(Not run)
```

---

Variogram.gls

*Calculate Semi-variogram for Residuals from a gls Object*

---

## Description

This method function calculates the semi-variogram for the residuals from a `gls` fit. The semi-variogram values are calculated for pairs of residuals within the same group level, if a grouping factor is present. If `collapse` is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (`robust = TRUE`) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

## Usage

```
## S3 method for class 'gls'
Variogram(object, distance, form, resType, data,
          na.action, maxDist, length.out, collapse, nint, breaks,
          robust, metric, ...)
```

## Arguments

<code>object</code>	an object inheriting from class " <code>gls</code> ", representing a generalized least squares fitted model.
<code>distance</code>	an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments <code>form</code> , <code>data</code> , and <code>metric</code> , unless <code>object</code> includes a <code>corSpatial</code> element, in which case the associated covariate (obtained with the <code>getCovariate</code> method) is used.
<code>form</code>	an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a <code> </code> operator in <code>form</code> ). Default is <code>~1</code> , implying that the observation order within the groups is used to obtain the distances.

<code>resType</code>	an optional character string specifying the type of residuals to be used. If "response", the "raw" residuals (observed - fitted) are used; else, if "pearson", the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if "normalized", the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to "pearson".
<code>data</code>	an optional data frame in which to interpret the variables in <code>form</code> . By default, the same data used to fit <code>object</code> is used.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
<code>maxDist</code>	an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.
<code>length.out</code>	an optional integer value. When <code>object</code> includes a <code>corSpatial</code> element, its semi-variogram values are calculated and this argument is used as the <code>length.out</code> argument to the corresponding <code>Variogram</code> method. Defaults to 50.
<code>collapse</code>	an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to "quantiles", the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if "fixed", the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if "none", no collapsing is used and the individual semi-variogram values are returned. Defaults to "quantiles".
<code>nint</code>	an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.
<code>robust</code>	an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If TRUE the robust estimator is used. Defaults to FALSE.
<code>breaks</code>	an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in <code>collapse</code> is ignored.
<code>metric</code>	an optional character string specifying the distance metric to be used. The currently available options are "euclidean" for the root sum-of-squares of distances; "maximum" for the maximum difference; and "manhattan" for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to "euclidean".
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

### Value

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its

corresponding semi-variogram is included in the returned value, as an attribute "modelVariog". The returned value inherits from class Variogram.

---

Variogram.lme

*Calculate Semi-variogram for Residuals from an lme Object*

---

### Description

This method function calculates the semi-variogram for the within-group residuals from an lme fit. The semi-variogram values are calculated for pairs of residuals within the same group. If collapse is different from "none", the individual semi-variogram values are collapsed using either a robust estimator (robust = TRUE) defined in Cressie (1993), or the average of the values within the same distance interval. The semi-variogram is useful for modeling the error term correlation structure.

### Usage

```
## S3 method for class 'lme'
Variogram(object, distance, form, resType, data,
          na.action, maxDist, length.out, collapse, nint, breaks,
          robust, metric, ...)
```

### Arguments

object	an object inheriting from class " <a href="#">lme</a> ", representing a fitted linear mixed-effects model.
distance	an optional numeric vector with the distances between residual pairs. If a grouping variable is present, only the distances between residual pairs within the same group should be given. If missing, the distances are calculated based on the values of the arguments form, data, and metric, unless object includes a corSpatial element, in which case the associated covariate (obtained with the getCovariate method) is used.

<code>form</code>	an optional one-sided formula specifying the covariate(s) to be used for calculating the distances between residual pairs and, optionally, a grouping factor for partitioning the residuals (which must appear to the right of a <code> </code> operator in <code>form</code> ). Default is <code>~1</code> , implying that the observation order within the groups is used to obtain the distances.
<code>resType</code>	an optional character string specifying the type of residuals to be used. If <code>"response"</code> , the <code>"raw"</code> residuals (observed - fitted) are used; else, if <code>"pearson"</code> , the standardized residuals (raw residuals divided by the corresponding standard errors) are used; else, if <code>"normalized"</code> , the normalized residuals (standardized residuals pre-multiplied by the inverse square-root factor of the estimated error correlation matrix) are used. Partial matching of arguments is used, so only the first character needs to be provided. Defaults to <code>"pearson"</code> .
<code>data</code>	an optional data frame in which to interpret the variables in <code>form</code> . By default, the same data used to fit <code>object</code> is used.
<code>na.action</code>	a function that indicates what should happen when the data contain NAs. The default action ( <code>na.fail</code> ) causes an error message to be printed and the function to terminate, if there are any incomplete observations.
<code>maxDist</code>	an optional numeric value for the maximum distance used for calculating the semi-variogram between two residuals. By default all residual pairs are included.
<code>length.out</code>	an optional integer value. When <code>object</code> includes a <code>corSpatial</code> element, its semi-variogram values are calculated and this argument is used as the <code>length.out</code> argument to the corresponding <code>Variogram</code> method. Defaults to 50.
<code>collapse</code>	an optional character string specifying the type of collapsing to be applied to the individual semi-variogram values. If equal to <code>"quantiles"</code> , the semi-variogram values are split according to quantiles of the distance distribution, with equal number of observations per group, with possibly varying distance interval lengths. Else, if <code>"fixed"</code> , the semi-variogram values are divided according to distance intervals of equal lengths, with possibly different number of observations per interval. Else, if <code>"none"</code> , no collapsing is used and the individual semi-variogram values are returned. Defaults to <code>"quantiles"</code> .
<code>nint</code>	an optional integer with the number of intervals to be used when collapsing the semi-variogram values. Defaults to 20.
<code>robust</code>	an optional logical value specifying if a robust semi-variogram estimator should be used when collapsing the individual values. If <code>TRUE</code> the robust estimator is used. Defaults to <code>FALSE</code> .
<code>breaks</code>	an optional numeric vector with the breakpoints for the distance intervals to be used in collapsing the semi-variogram values. If not missing, the option specified in <code>collapse</code> is ignored.
<code>metric</code>	an optional character string specifying the distance metric to be used. The currently available options are <code>"euclidean"</code> for the root sum-of-squares of distances; <code>"maximum"</code> for the maximum difference; and <code>"manhattan"</code> for the sum of the absolute differences. Partial matching of arguments is used, so only the first three characters need to be provided. Defaults to <code>"euclidean"</code> .
<code>...</code>	some methods for this generic require additional arguments. None are used in this method.

**Value**

a data frame with columns `variog` and `dist` representing, respectively, the semi-variogram values and the corresponding distances. If the semi-variogram values are collapsed, an extra column, `n.pairs`, with the number of residual pairs used in each semi-variogram calculation, is included in the returned data frame. If `object` includes a `corSpatial` element, a data frame with its corresponding semi-variogram is included in the returned value, as an attribute `"modelVariog"`. The returned value inherits from class `Variogram`.

```

---

varPower

*Power Variance Function*

---

**Description**

This function is a constructor for the `varPower` class, representing a power variance function structure. Letting  $v$  denote the variance covariate and  $\sigma^2(v)$  denote the variance function evaluated at  $v$ , the power variance function is defined as  $\sigma^2(v) = |v|^{2\theta}$ , where  $\theta$  is the variance function coefficient. When a grouping factor is present, a different  $\theta$  is used for each factor level.

**Usage**

```
varPower(value, form, fixed)
```

**Arguments**

<code>value</code>	an optional numeric vector, or list of numeric values, with the variance function coefficients. Value must have length one, unless a grouping factor is specified in <code>form</code> . If <code>value</code> has length greater than one, it must have names which identify its elements to the levels of the grouping factor defined in <code>form</code> . If a grouping factor is present in <code>form</code> and <code>value</code> has length one, its value will be assigned to all grouping levels. Default is <code>numeric(0)</code> , which results in a vector of zeros of appropriate length being assigned to the coefficients when object is initialized (corresponding to constant variance equal to one).
--------------------	--

<code>form</code>	an optional one-sided formula of the form $\sim v$ , or $\sim v \mid g$ , specifying a variance covariate $v$ and, optionally, a grouping factor $g$ for the coefficients. The variance covariate must evaluate to a numeric vector and may involve expressions using <code>"."</code> , representing a fitted model object from which fitted values ( <code>fitted(.)</code> ) and residuals ( <code>resid(.)</code> ) can be extracted (this allows the variance covariate to be updated during the optimization of an object function). When a grouping factor is present in <code>form</code> , a different coefficient value is used for each of its levels. Several grouping variables may be simultaneously specified, separated by the <code>*</code> operator, like in $\sim v \mid g1 * g2 * g3$ . In this case, the levels of each grouping variable are pasted together and the resulting factor is used to group the observations. Defaults to $\sim fitted(.)$ representing a variance covariate given by the fitted values of a fitted model object and no grouping factor.
<code>fixed</code>	an optional numeric vector, or list of numeric values, specifying the values at which some or all of the coefficients in the variance function should be fixed. If a grouping factor is specified in <code>form</code> , <code>fixed</code> must have names identifying which coefficients are to be fixed. Coefficients included in <code>fixed</code> are not allowed to vary during the optimization of an objective function. Defaults to <code>NULL</code> , corresponding to no fixed coefficients.

**Value**

a `varPower` object representing a power variance function structure, also inheriting from class `varFunc`.

---

`varWeights`

*Extract Variance Function Weights*

---

**Description**

The inverse of the standard deviations corresponding to the variance function structure represented by `object` are returned.

**Usage**

```
varWeights(object)
```

**Arguments**

`object` an object inheriting from class `varFunc`, representing a variance function structure.

**Value**

if `object` has a `weights` attribute, its value is returned; else `NULL` is returned.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

---

```
varWeights.glsStruct
```

*Variance Weights for glsStruct Object*

---

**Description**

If `object` includes a `varStruct` component, the inverse of the standard deviations of the variance function structure represented by the corresponding `varFunc` object are returned; else, a vector of ones of length equal to the number of observations in the data frame used to fit the associated linear model is returned.

**Usage**

```
## S3 method for class 'glsStruct'
varWeights(object)
```

**Arguments**

`object` an object inheriting from class `"glsStruct"`, representing a list of linear model components, such as `corStruct` and `"varFunc"` objects.

**Value**

if `object` includes a `varStruct` component, a vector with the corresponding variance weights; else, or a vector of ones.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

[.pdMat

*Subscript a pdMat Object***Description**

This method function extracts sub-matrices from the positive-definite matrix represented by `x`.

**Usage**

```
## S3 method for class 'pdMat'
x[i, j, drop = TRUE]
## S3 replacement method for class 'pdMat'
x[i, j] <- value
```

**Arguments**

<code>x</code>	an object inheriting from class " <a href="#">pdMat</a> " representing a positive-definite matrix.
<code>i, j</code>	optional subscripts applying respectively to the rows and columns of the positive-definite matrix represented by <code>object</code> . When <code>i</code> ( <code>j</code> ) is omitted, all rows (columns) are extracted.
<code>drop</code>	a logical value. If <code>TRUE</code> , single rows or columns are converted to vectors. If <code>FALSE</code> the returned value retains its matrix representation.
<code>value</code>	a vector, or matrix, with the replacement values for the relevant piece of the matrix represented by <code>x</code> .

**Value**

if `i` and `j` are identical, the returned value will be `pdMat` object with the same class as `x`. Otherwise, the returned value will be a matrix. In the case a single row (or column) is selected, the returned value may be converted to a vector, according to the rules above.

**Author(s)**

José Pinheiro and Douglas Bates <bates@stat.wisc.edu>

**Examples**

```
pd1 <- pdSymm(diag(3))
pd1[1, , drop = FALSE]
pd1[1:2, 1:2] <- 3 * diag(2)
```

## Chapter 26

# The nnet package

---

`class.ind`

*Generates Class Indicator Matrix from a Factor*

---

### Description

Generates a class indicator function from a given factor.

### Usage

```
class.ind(cl)
```

### Arguments

`cl` factor or vector of classes for cases.

### Value

a matrix which is zero except for the column corresponding to the class.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### Examples

```
# The function is currently defined as
class.ind <- function(cl)
{
  n <- length(cl)
  cl <- as.factor(cl)
  x <- matrix(0, n, length(levels(cl)) )
  x[(1:n) + n*(unclass(cl)-1)] <- 1
  dimnames(x) <- list(names(cl), levels(cl))
  x
}
```

multinom

*Fit Multinomial Log-linear Models***Description**

Fits multinomial log-linear models via neural networks.

**Usage**

```
multinom(formula, data, weights, subset, na.action,
         contrasts = NULL, Hess = FALSE, summ = 0, censored = FALSE,
         model = FALSE, ...)
```

**Arguments**

<code>formula</code>	a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor or a matrix with <code>K</code> columns, which will be interpreted as counts for each of <code>K</code> classes. A log-linear model is fitted, with coefficients zero for the first class. An offset can be included: it should be a numeric matrix with <code>K</code> columns if the response is either a matrix with <code>K</code> columns or a factor with <code>K &gt;= 2</code> classes, or a numeric vector for a response factor with 2 levels. See the documentation of <code>formula()</code> for other details.
<code>data</code>	an optional data frame in which to interpret the variables occurring in <code>formula</code> .
<code>weights</code>	optional case weights in fitting.
<code>subset</code>	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
<code>na.action</code>	a function to filter missing data.
<code>contrasts</code>	a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
<code>Hess</code>	logical for whether the Hessian (the observed/expected information matrix) should be returned.
<code>summ</code>	integer; if non-zero summarize by deleting duplicate rows and adjust weights. Methods 1 and 2 differ in speed (2 uses C); method 3 also combines rows with the same X and different Y, which changes the baseline for the deviance.
<code>censored</code>	If Y is a matrix with <code>K</code> columns, interpret the entries as one for possible classes, zero for impossible classes, rather than as counts.
<code>model</code>	logical. If true, the model frame is saved as component <code>model</code> of the returned object.
<code>...</code>	additional arguments for <code>nnet</code>

**Details**

`multinom` calls `nnet`. The variables on the rhs of the formula should be roughly scaled to [0,1] or the fit will be slow or may not converge at all.

**Value**

A `nnet` object with additional components:

<code>deviance</code>	the residual deviance, compared to the full saturated model (that explains individual observations exactly). Also, minus twice log-likelihood.
<code>edf</code>	the (effective) number of degrees of freedom used by the model
<code>AIC</code>	the AIC for this fit.
<code>Hessian</code>	(if <code>Hess</code> is <code>true</code> ).
<code>model</code>	(if <code>model</code> is <code>true</code> ).

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

[nnet](#)

**Examples**

```
options(contrasts = c("contr.treatment", "contr.poly"))
library(MASS)
example(birthwt)
(bwt.mu <- multinom(low ~ ., bwt))
```

---

nnet

*Fit Neural Networks*

---

**Description**

Fit single-hidden-layer neural network, possibly with skip-layer connections.

**Usage**

```
nnet(x, ...)
```

## S3 method for class 'formula'

```
nnet(formula, data, weights, ...,
      subset, na.action, contrasts = NULL)
```

## Default S3 method:

```
nnet(x, y, weights, size, Wts, mask,
      linout = FALSE, entropy = FALSE, softmax = FALSE,
      censored = FALSE, skip = FALSE, rang = 0.7, decay = 0,
      maxit = 100, Hess = FALSE, trace = TRUE, MaxNWts = 1000,
      abstol = 1.0e-4, reltol = 1.0e-8, ...)
```

**Arguments**

<code>formula</code>	A formula of the form <code>class ~ x1 + x2 + ...</code> .
<code>x</code>	matrix or data frame of <code>x</code> values for examples.
<code>y</code>	matrix or data frame of target values for examples.
<code>weights</code>	(case) weights for each example – if missing defaults to 1.
<code>size</code>	number of units in the hidden layer. Can be zero if there are skip-layer units.
<code>data</code>	Data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>subset</code>	An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
<code>contrasts</code>	a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
<code>Wts</code>	initial parameter vector. If missing chosen at random.
<code>mask</code>	logical vector indicating which parameters should be optimized (default all).
<code>linout</code>	switch for linear output units. Default logistic output units.
<code>entropy</code>	switch for entropy (= maximum conditional likelihood) fitting. Default by least-squares.
<code>softmax</code>	switch for softmax (log-linear model) and maximum conditional likelihood fitting. <code>linout</code> , <code>entropy</code> , <code>softmax</code> and <code>censored</code> are mutually exclusive.
<code>censored</code>	A variant on <code>softmax</code> , in which non-zero targets mean possible classes. Thus for <code>softmax</code> a row of (0, 1, 1) means one example each of classes 2 and 3, but for <code>censored</code> it means one example whose class is only known to be 2 or 3.
<code>skip</code>	switch to add skip-layer connections from input to output.
<code>rang</code>	Initial random weights on <code>[-rang, rang]</code> . Value about 0.5 unless the inputs are large, in which case it should be chosen so that <code>rang * max( x )</code> is about 1.
<code>decay</code>	parameter for weight decay. Default 0.
<code>maxit</code>	maximum number of iterations. Default 100.
<code>Hess</code>	If true, the Hessian of the measure of fit at the best set of weights found is returned as component <code>Hessian</code> .
<code>trace</code>	switch for tracing optimization. Default TRUE.
<code>MaxNWts</code>	The maximum allowable number of weights. There is no intrinsic limit in the code, but increasing <code>MaxNWts</code> will probably allow fits that are very slow and time-consuming.
<code>abstol</code>	Stop if the fit criterion falls below <code>abstol</code> , indicating an essentially perfect fit.
<code>reltol</code>	Stop if the optimizer is unable to reduce the fit criterion by a factor of at least <code>1 - reltol</code> .
<code>...</code>	arguments passed to or from other methods.

## Details

If the response in `formula` is a factor, an appropriate classification network is constructed; this has one output and entropy fit if the number of levels is two, and a number of outputs equal to the number of classes and a softmax output stage for more levels. If the response is not a factor, it is passed on unchanged to `nnet.default`.

Optimization is done via the BFGS method of `optim`.

## Value

object of class "nnet" or "nnet.formula". Mostly internal structure, but has components

<code>wts</code>	the best set of weights found
<code>value</code>	value of fitting criterion plus weight decay term.
<code>fitted.values</code>	the fitted values for the training data.
<code>residuals</code>	the residuals for the training data.
<code>convergence</code>	1 if the maximum number of iterations was reached, otherwise 0.

              decay = 5e-4, maxit = 200)
table(ird$species[-samp], predict(ir.nn2, ird[-samp,], type = "class"))
```

nnetHess

*Evaluates Hessian for a Neural Network***Description**

Evaluates the Hessian (matrix of second derivatives) of the specified neural network. Normally called via argument `Hess=TRUE` to `nnet` or via `vcov.multinom`.

**Usage**

```
nnetHess(net, x, y, weights)
```

**Arguments**

<code>net</code>	object of class <code>nnet</code> as returned by <code>nnet</code> .
<code>x</code>	training data.
<code>y</code>	classes for training data.
<code>weights</code>	the (case) weights used in the <code>nnet</code> fit.

**Value**

square symmetric matrix of the Hessian evaluated at the weights stored in the net.

---

predict.nnet	<i>Predict New Examples by a Trained Neural Net</i>
--------------	---

---

## Description

Predict new examples by a trained neural net.

## Usage

```
## S3 method for class 'nnet'
predict(object, newdata, type = c("raw", "class"), ...)
```

## Arguments

object	an object of class <code>nnet</code> as returned by <code>nnet</code> .
newdata	matrix or data frame of test examples. A vector is considered to be a row vector comprising a single case.
type	Type of output
...	arguments passed to or from other methods.

## Details

This function is a method for the generic function `predict()` for class `"nnet"`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.nnet(x)` regardless of the class of the object.

## Value

If `type = "raw"`, the matrix of values returned by the trained network; if `type = "class"`, the corresponding class (which is probably only useful if the net was generated by `nnet.formula`).

## References

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.

which.is.max

*Find Maximum Position in Vector*

---

## Description

Find the maximum position in a vector, breaking ties at random.

## Usage

```
which.is.max(x)
```

## Arguments

x                      a vector

## Details

Ties are broken at random.

## Value

index of a maximal value.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## See Also

[max.col](#), [which.max](#) which takes the first of ties.

## Examples

```

## Not run: ## this is incomplete
pred <- predict(nnet, test)
table(true, apply(pred, 1, which.is.max))

## End(Not run)

```

## Chapter 27

# The rpart package

---

<code>car.test.frame</code>	<i>Automobile Data from 'Consumer Reports' 1990</i>
-----------------------------	---

---

### Description

The `car.test.frame` data frame has 60 rows and 8 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*. This is part of a larger dataset, some columns of which are given in [cu.summary](#).

### Usage

```
car.test.frame
```

### Format

This data frame contains the following columns:

`Price` a numeric vector giving the list price in US dollars of a standard model

`Country of origin`, a factor with levels 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'

`Reliability` a numeric vector coded 1 to 5.

`Mileage` fuel consumption miles per US gallon, as tested.

`Type` a factor with levels Compact Large Medium Small Sporty Van

`Weight` kerb weight in pounds.

`Disp.` the engine capacity (displacement) in litres.

`HP` the net horsepower of the vehicle.

### Source

*Consumer Reports*, April, 1990, pp. 235–288 quoted in

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA, pp. 46–47.

[car90](#), [cu.summary](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)
```

---

car90

---

*Automobile Data from 'Consumer Reports' 1990*

---

**Description**

Data on 111 cars, taken from pages 235–255, 281–285 and 287–288 of the April 1990 *Consumer Reports* Magazine.

**Usage**

```
data(car90)
```

**Format**

The data frame contains the following columns

**Country** a factor giving the country in which the car was manufactured

**Disp** engine displacement in cubic inches

**Disp2** engine displacement in liters

**Eng.Rev** engine revolutions per mile, or engine speed at 60 mph

**Front.Hd** distance between the car's head-liner and the head of a 5 ft. 9 in. front seat passenger, in inches, as measured by CU

**Frt.Leg.Room** maximum front leg room, in inches, as measured by CU

**Frt.Shld** front shoulder room, in inches, as measured by CU

**Gear.Ratio** the overall gear ratio, high gear, for manual transmission

**Gear2** the overall gear ratio, high gear, for automatic transmission

**HP** net horsepower

**HP.revs** the red line—the maximum safe engine speed in rpm

**Height** height of car, in inches, as supplied by manufacturer

**Length** overall length, in inches, as supplied by manufacturer

**Luggage** luggage space

**Mileage** a numeric vector of gas mileage in miles/gallon as tested by CU; contains NAs.

**Model2** alternate name, if the car was sold under two labels

**Price** list price with standard equipment, in dollars

**Rear.Hd** distance between the car's head-liner and the head of a 5 ft 9 in. rear seat passenger, in inches, as measured by CU

**Rear.Seating** rear fore-and-aft seating room, in inches, as measured by CU

**RearShld** rear shoulder room, in inches, as measured by CU

**Reliability** an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better': contains NAs.

**Rim** factor giving the rim size

**Sratio.m** Number of turns of the steering wheel required for a turn of 30 foot radius, manual steering

**Sratio.p** Number of turns of the steering wheel required for a turn of 30 foot radius, power steering

**Steering** steering type offered: manual, power, or both

**Tank** fuel refill capacity in gallons

**Tires** factor giving tire size

**Trans1** manual transmission, a factor with levels "", 'man.4', 'man.5' and 'man.6'

**Trans2** automatic transmission, a factor with levels "", 'auto.3', 'auto.4', and 'auto.CVT'. No car is missing both the manual and automatic transmission variables, but several had both as options

**Turning** the radius of the turning circle in feet

**Type** a factor giving the general type of car. The levels are: 'Small', 'Sporty', 'Compact', 'Medium', 'Large', 'Van'

**Weight** an order statistic giving the relative weights of the cars; 1 is the lightest and 111 is the heaviest

**Wheel.base** length of wheelbase, in inches, as supplied by manufacturer

**Width** width of car, in inches, as supplied by manufacturer

## Source

This is derived (with permission) from the data set `car.all` in S-PLUS, but with some further clean up of variable names and definitions.

## See Also

[car.test.frame](#), [cu.summary](#) for extracts from other versions of the dataset.

## Examples

```
data(car90)
plot(car90$Price/1000, car90$Weight,
     xlab = "Price (thousands)", ylab = "Weight (lbs)")
mlowess <- function(x, y, ...) {
  keep <- !(is.na(x) | is.na(y))
  lowess(x[keep], y[keep], ...)
}
with(car90, lines(mlowess(Price/1000, Weight, f = 0.5)))
```

---

cu.summary

*Automobile Data from 'Consumer Reports' 1990*

---

## Description

The `cu.summary` data frame has 117 rows and 5 columns, giving data on makes of cars taken from the April, 1990 issue of *Consumer Reports*.

## Usage

```
cu.summary
```

## Format

This data frame contains the following columns:

`Price` a numeric vector giving the list price in US dollars of a standard model

`Country of origin`, a factor with levels 'Brazil', 'England', 'France', 'Germany', 'Japan', 'Japan/USA', 'Korea', 'Mexico', 'Sweden' and 'USA'

`Reliability` an ordered factor with levels 'Much worse' < 'worse' < 'average' < 'better' < 'Much better'

`Mileage` fuel consumption miles per US gallon, as tested.

`Type` a factor with levels Compact Large Medium Small Sporty Van

```

---

kyphosis

*Data on Children who have had Corrective Spinal Surgery*

---

**Description**

The `kyphosis` data frame has 81 rows and 4 columns. representing data on children who have had corrective spinal surgery

**Usage**

```
kyphosis
```

**Format**

This data frame contains the following columns:

`Kyphosis` a factor with levels `absent` `present` indicating if a kyphosis (a type of deformation) was present after the operation.

`Age` in months

`Number` the number of vertebrae involved

`Start` the number of the first (topmost) vertebra operated on.

**Source**

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
             parms = list(prior = c(0.65, 0.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data=kyphosis,
             control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = TRUE)
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

---

labels.rpart

*Create Split Labels For an Rpart Object*

---

**Description**

This function provides labels for the branches of an `rpart` tree.

**Usage**

```
## S3 method for class 'rpart'
labels(object, digits = 4, minlength = 1L, pretty, collapse = TRUE, ...)
```

**Arguments**

<code>object</code>	fitted model object of class <code>"rpart"</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>digits</code>	the number of digits to be used for numeric values. All of the <code>rpart</code> functions that call labels explicitly set this value, with <code>options("digits")</code> as the default.
<code>minlength</code>	the minimum length for abbreviation of character or factor variables. If 0 no abbreviation is done; if 1 single English letters are used, first lower case than upper case (with a maximum of 52 levels). If the value is greater than , the <a href="#">abbreviate</a> function is used, passed the <code>minlength</code> argument.
<code>pretty</code>	an argument included for compatibility with the <b>tree</b> package: <code>pretty = 0</code> implies <code>minlength = 0L</code> , <code>pretty = NULL</code> implies <code>minlength = 1L</code> , and <code>pretty = TRUE</code> implies <code>minlength = 4L</code> .
<code>collapse</code>	logical. The returned set of labels is always of the same length as the number of nodes in the tree. If <code>collapse = TRUE</code> (default), the returned value is a vector of labels for the branch leading into each node, with <code>"root"</code> as the label for the top node. If <code>FALSE</code> , the returned value is a two column matrix of labels for the left and right branches leading out from each node, with <code>"leaf"</code> as the branch labels for terminal nodes.
<code>...</code>	optional arguments to <code>abbreviate</code> .

**Value**

Vector of split labels (`collapse = TRUE`) or matrix of left and right splits (`collapse = FALSE`) for the supplied `rpart` object. This function is called by printing methods for `rpart` and is not intended to be called directly by the users.

**See Also**

[abbreviate](#)

---

`meanvar.rpart`

*Mean-Variance Plot for an Rpart Object*

---

**Description**

Creates a plot on the current graphics device of the deviance of the node divided by the number of observations at the node. Also returns the node number.

**Usage**

```
meanvar(tree, ...)
```

```
## S3 method for class 'rpart'
```

```
meanvar(tree, xlab = "ave(y)", ylab = "ave(deviance)", ...)
```

**Arguments**

<code>tree</code>	fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>xlab</code>	x-axis label for the plot.
<code>ylab</code>	y-axis label for the plot.
<code>...</code>	additional graphical parameters may be supplied as arguments to this function.

**Value**

an invisible list containing the following vectors is returned.

<code>x</code>	fitted value at terminal nodes ( <code>yval</code> ).
<code>y</code>	deviance of node divided by number of observations at node.
<code>label</code>	node number.

**Side Effects**

a plot is put on the current graphics device.

**See Also**

[plot.rpart](#).

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
meanvar(z.auto, log = 'xy')
```

---

`na.rpart`*Handles Missing Values in an Rpart Object*

---

**Description**

Handles missing values in an "rpart" object.

**Usage**

```
na.rpart(x)
```

**Arguments**

<code>x</code>	a model frame.
----------------	----------------

**Details**

Default function that handles missing values when calling the function `rpart`.

It omits cases where part of the response is missing or all the explanatory variables are missing.

---

path.rpart	<i>Follow Paths to Selected Nodes of an Rpart Object</i>
------------	--

---

**Description**

Returns a names list where each element contains the splits on the path from the root to the selected nodes.

**Usage**

```
path.rpart(tree, nodes, pretty = 0, print.it = TRUE)
```

**Arguments**

tree	fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
nodes	an integer vector containing indices (node numbers) of all nodes for which paths are desired. If missing, user selects nodes as described below.
pretty	an integer denoting the extent to which factor levels in split labels will be abbreviated. A value of (0) signifies no abbreviation. A <code>NULL</code> , the default, signifies using elements of letters to represent the different factor levels.
print.it	Logical. Denotes whether paths will be printed out as nodes are interactively selected. Irrelevant if <code>nodes</code> argument is supplied.

**Details**

The function has a required argument as an `rpart` object and a list of nodes as optional arguments. Omitting a list of nodes will cause the function to wait for the user to select nodes from the dendrogram. It will return a list, with one component for each node specified or selected. The component contains the sequence of splits leading to that node. In the graphical interaction, the individual paths are printed out as nodes are selected.

**Value**

A named (by node) list, each element of which contains all the splits on the path from the root to the specified or selected nodes.

**Graphical Interaction**

A dendrogram of the `rpart` object is expected to be visible on the graphics device, and a graphics input device (e.g. a mouse) is required. Clicking (the selection button) on a node selects that node. This process may be repeated any number of times. Clicking the exit button will stop the selection process and return the list of paths.

**References**

This function was modified from `path.tree` in S.

**See Also**

[rpart](#)

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
print(fit)
path.rpart(fit, node = c(11, 22))
```

plot.rpart

*Plot an Rpart Object***Description**

Plots an rpart object on the current graphics device.

**Usage**

```
## S3 method for class 'rpart'
plot(x, uniform = FALSE, branch = 1, compress = FALSE, nspace,
      margin = 0, minbranch = 0.3, ...)
```

**Arguments**

<code>x</code>	a fitted object of class "rpart", containing a classification, regression, or rate tree.
<code>uniform</code>	if TRUE, uniform vertical spacing of the nodes is used; this may be less cluttered when fitting a large plot onto a page. The default is to use a non-uniform spacing proportional to the error in the fit.
<code>branch</code>	controls the shape of the branches from parent to child node. Any number from 0 to 1 is allowed. A value of 1 gives square shouldered branches, a value of 0 give V shaped branches, with other values being intermediate.
<code>compress</code>	if FALSE, the leaf nodes will be at the horizontal plot coordinates of 1:nleaves. If TRUE, the routine attempts a more compact arrangement of the tree. The compaction algorithm assumes <code>uniform=TRUE</code> ; surprisingly, the result is usually an improvement even when that is not the case.
<code>nspace</code>	the amount of extra space between a node with children and a leaf, as compared to the minimal space between leaves. Applies to compressed trees only. The default is the value of <code>branch</code> .
<code>margin</code>	an extra fraction of white space to leave around the borders of the tree. (Long labels sometimes get cut off by the default computation).
<code>minbranch</code>	set the minimum length for a branch to <code>minbranch</code> times the average branch length. This parameter is ignored if <code>uniform=TRUE</code> . Sometimes a split will give very little improvement, or even (in the classification case) no improvement at all. A tree with branch lengths strictly proportional to improvement leaves no room to squeeze in node labels.
<code>...</code>	arguments to be passed to or from other methods.

**Details**

This function is a method for the generic function `plot`, for objects of class `rpart`. The y-coordinate of the top node of the tree will always be 1.

**Value**

The coordinates of the nodes are returned as a list, with components `x` and `y`.

**Side Effects**

An unlabeled plot is produced on the current graphics device: one being opened if needed.

In order to build up a plot in the usual S style, e.g., a separate `text` command for adding labels, some extra information about the plot needs be retained. This is kept in an environment in the package.

**See Also**

`rpart`, `text.rpart`

**Examples**

```
fit <- rpart(Price ~ Mileage + Type + Country, cu.summary)
par(xpd = TRUE)
plot(fit, compress = TRUE)
text(fit, use.n = TRUE)
```

---

plotcp

*Plot a Complexity Parameter Table for an Rpart Fit*

---

**Description**

Gives a visual representation of the cross-validation results in an `rpart` object.

**Usage**

```
plotcp(x, minline = TRUE, lty = 3, col = 1,
       upper = c("size", "splits", "none"), ...)
```

**Arguments**

<code>x</code>	an object of class "rpart"
<code>minline</code>	whether a horizontal line is drawn 1SE above the minimum of the curve.
<code>lty</code>	line type for this line
<code>col</code>	colour for this line
<code>upper</code>	what is plotted on the top axis: the size of the tree (the number of leaves), the number of splits or nothing.
<code>...</code>	additional plotting parameters

**Details**

The set of possible cost-complexity prunings of a tree from a nested set. For the geometric means of the intervals of values of `cp` for which a pruning is optimal, a cross-validation has (usually) been done in the initial construction by `rpart`. The `cptable` in the fit contains the mean and standard deviation of the errors in the cross-validated prediction against each of the geometric means, and these are plotted by this function. A good choice of `cp` for pruning is often the leftmost value for which the mean lies below the horizontal line.

**Value**

None.

**Side Effects**

A plot is produced on the current graphical device.

**See Also**

[rpart](#), [printcp](#), [rpart.object](#)

---

post.rpart

*PostScript Presentation Plot of an Rpart Object*

---

**Description**

Generates a PostScript presentation plot of an `rpart` object.

**Usage**

```
post(tree, ...)

## S3 method for class 'rpart'
post(tree, title.,
      filename = paste(deparse(substitute(tree)), ".ps", sep = ""),
      digits = getOption("digits") - 2, pretty = TRUE,
      use.n = TRUE, horizontal = TRUE, ...)
```

**Arguments**

<code>tree</code>	fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>title.</code>	a title which appears at the top of the plot. By default, the name of the <code>rpart</code> endpoint is printed out.
<code>filename</code>	ASCII file to contain the output. By default, the name of the file is the name of the object given by <code>rpart</code> (with the suffix <code>.ps</code> added). If <code>filename = ""</code> , the plot appears on the current graphical device.
<code>digits</code>	number of significant digits to include in numerical data.
<code>pretty</code>	an integer denoting the extent to which factor levels will be abbreviated in the character strings defining the splits; (0) signifies no abbreviation of levels. A NULL signifies using elements of letters to represent the different factor levels. The default (TRUE) indicates the maximum possible abbreviation.
<code>use.n</code>	Logical. If TRUE (default), adds to label ( <code>\#events level1/\#events level2/etc.</code> for method <code>class</code> , <code>n</code> for method <code>anova</code> , and <code>\#events/n</code> for methods <code>poisson</code> and <code>exp</code> ).
<code>horizontal</code>	Logical. If TRUE (default), plot is horizontal. If FALSE, plot appears as landscape.
<code>...</code>	other arguments to the <code>postscript</code> function.

## Details

The plot created uses the functions `plot.rpart` and `text.rpart` (with the `fancy` option). The settings were chosen because they looked good to us, but other options may be better, depending on the `rpart` object. Users are encouraged to write their own function containing favorite options.

## Side Effects

a plot of `rpart` is created using the `postscript` driver, or the current device if `filename = ""`.

## See Also

`plot.rpart`, `rpart`, `text.rpart`, `abbreviate`

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
post(z.auto, file = "") # display tree on active device
# now construct postscript version on file "pretty.ps"
# with no title
post(z.auto, file = "pretty.ps", title = " ")
z.hp <- rpart(Mileage ~ Weight + HP, car.test.frame)
post(z.hp)
```

---

`predict.rpart`

*Predictions from a Fitted Rpart Object*

---

## Description

Returns a vector of predicted responses from a fitted `rpart` object.

## Usage

```
## S3 method for class 'rpart'
predict(object, newdata,
        type = c("vector", "prob", "class", "matrix"),
        na.action = na.pass, ...)
```

## Arguments

<code>object</code>	fitted model object of class <code>"rpart"</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>newdata</code>	data frame containing the values at which predictions are required. The predictors referred to in the right side of <code>formula(object)</code> must be present by name in <code>newdata</code> . If missing, the fitted values are returned.
<code>type</code>	character string denoting the type of predicted value returned. If the <code>rpart</code> object is a classification tree, then the default is to return <code>prob</code> predictions, a matrix whose columns are the probability of the first, second, etc. class. (This agrees with the default behavior of <code>tree</code> ). Otherwise, a vector result is returned.

`na.action` a function to determine what should be done with missing values in `newdata`. The default is to pass them down the tree using surrogates in the way selected when the model was built. Other possibilities are `na.omit` and `na.fail`.

`...` further arguments passed to or from other methods.

## Details

This function is a method for the generic function `predict` for class `"rpart"`. It can be invoked by calling `predict` for an object of the appropriate class, or directly by calling `predict.rpart` regardless of the class of the object.

## Value

A new object is obtained by dropping `newdata` down the object. For factor predictors, if an observation contains a level not used to grow the tree, it is left at the deepest possible node and `frame$yval` at the node is the prediction.

If `type = "vector"`:

vector of predicted responses. For regression trees this is the mean response at the node, for Poisson trees it is the estimated response rate, and for classification trees it is the predicted class (as a number).

If `type = "prob"`:

(for a classification tree) a matrix of class probabilities.

If `type = "matrix"`:

a matrix of the full responses (`frame$yval2` if this exists, otherwise `frame$yval`). For regression trees, this is the mean response, for Poisson trees it is the response rate and the number of events at that node in the fitted tree, and for classification trees it is the concatenation of at least the predicted class, the class counts at that node in the fitted tree, and the class probabilities (some versions of **rpart** may contain further columns).

If `type = "class"`:

(for a classification tree) a factor of classifications based on the responses.

## See Also

`predict, rpart.object`

## Examples

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
predict(z.auto)

fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
predict(fit, type = "prob") # class probabilities (default)
predict(fit, type = "vector") # level numbers
predict(fit, type = "class") # factor
predict(fit, type = "matrix") # level number, class frequencies, probabilities

sub <- c(sample(1:50, 25), sample(51:100, 25), sample(101:150, 25))
fit <- rpart(Species ~ ., data = iris, subset = sub)
fit
table(predict(fit, iris[-sub,], type = "class"), iris[-sub, "Species"])
```

---

print.rpart	<i>Print an Rpart Object</i>
-------------	------------------------------

---

## Description

This function prints an `rpart` object. It is a method for the generic function `print` of class `"rpart"`.

## Usage

```
## S3 method for class 'rpart'
print(x, minlength = 0, spaces = 2, cp, digits = getOption("digits"), ...)
```

## Arguments

<code>x</code>	fitted model object of class <code>"rpart"</code> . This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>minlength</code>	Controls the abbreviation of labels: see <a href="#">labels.rpart</a> .
<code>spaces</code>	the number of spaces to indent nodes of increasing depth.
<code>digits</code>	the number of digits of numbers to print.
<code>cp</code>	prune all nodes with a complexity less than <code>cp</code> from the printout. Ignored if unspecified.
<code>...</code>	arguments to be passed to or from other methods.

## Details

This function is a method for the generic function `print` for class `"rpart"`. It can be invoked by calling `print` for an object of the appropriate class, or directly by calling `print.rpart` regardless of the class of the object.

## Side Effects

A semi-graphical layout of the contents of `x$frame` is printed. Indentation is used to convey the tree topology. Information for each node includes the node number, split, size, deviance, and fitted value. For the `"class"` method, the class probabilities are also printed.

---

printcp

---

*Displays CP table for Fitted Rpart Object*

---

## Description

Displays the cp table for fitted rpart object.

## Usage

```
printcp(x, digits = getOption("digits") - 2)
```

## Arguments

x	fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
digits	the number of digits of numbers to print.

## Details

Prints a table of optimal prunings based on a complexity parameter.

-------------	---

---

**Description**

Determines a nested sequence of subtrees of the supplied `rpart` object by recursively snipping off the least important splits, based on the complexity parameter (`cp`).

**Usage**

```
prune(tree, ...)
```

```
## S3 method for class 'rpart'
```

```
prune(tree, cp, ...)
```

**Arguments**

<code>tree</code>	fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
<code>cp</code>	Complexity parameter to which the <code>rpart</code> object will be trimmed.
<code>...</code>	further arguments passed to or from other methods.

**Value**

A new `rpart` object that is trimmed to the value `cp`.

**See Also**

[rpart](#)

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
zp <- prune(z.auto, cp = 0.1)
plot(zp) #plot smaller rpart object
```

---

residuals.rpart	<i>Residuals From a Fitted Rpart Object</i>
-----------------	---

---

**Description**

Method for residuals for an `rpart` object.

**Usage**

```
## S3 method for class 'rpart'
```

```
residuals(object, type = c("usual", "pearson", "deviance"), ...)
```

**Arguments**

<code>object</code>	fitted model object of class "rpart".
<code>type</code>	Indicates the type of residual desired. For regression or anova trees all three residual definitions reduce to $y - \text{fitted}$ . This is the residual returned for <code>user</code> method trees as well. For classification trees the <code>usual</code> residuals are the misclassification losses $L(\text{actual}, \text{predicted})$ where $L$ is the loss matrix. With default losses this residual is 0/1 for correct/incorrect classification. The <code>pearson</code> residual is $(1 - \text{fitted})/\sqrt{\text{fitted}(1 - \text{fitted})}$ and the <code>deviance</code> residual is $\sqrt{\text{minus twice log-arithm of fitted}}$ . For <code>poisson</code> and <code>exp</code> (or survival) trees, the <code>usual</code> residual is the observed - expected number of events. The <code>pearson</code> and <code>deviance</code> residuals are as defined in McCullagh and Nelder.
<code>...</code>	further arguments passed to or from other methods.

**Value**

Vector of residuals of type `type` from a fitted `rpart` object.

**References**

McCullagh P. and Nelder, J. A. (1989) *Generalized Linear Models*. London: Chapman and Hall.

**Examples**

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
            data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

rpart

*Recursive Partitioning and Regression Trees***Description**

Fit a `rpart` model

**Usage**

```
rpart(formula, data, weights, subset, na.action = na.rpart, method,
      model = FALSE, x = FALSE, y = TRUE, parms, control, cost, ...)
```

**Arguments**

<code>formula</code>	a <a href="#">formula</a> , with a response but no interaction terms. If this is a data frame, that is taken as the model frame (see <a href="#">model.frame</a> ) .
<code>data</code>	an optional data frame in which to interpret the variables named in the formula.
<code>weights</code>	optional case weights.
<code>subset</code>	optional expression saying that only a subset of the rows of the data should be used in the fit.

<code>na.action</code>	the default action deletes all observations for which <code>y</code> is missing, but keeps those in which one or more predictors are missing.
<code>method</code>	one of "anova", "poisson", "class" or "exp". If <code>method</code> is missing then the routine tries to make an intelligent guess. If <code>y</code> is a survival object, then <code>method = "exp"</code> is assumed, if <code>y</code> has 2 columns then <code>method = "poisson"</code> is assumed, if <code>y</code> is a factor then <code>method = "class"</code> is assumed, otherwise <code>method = "anova"</code> is assumed. It is wisest to specify the method directly, especially as more criteria may added to the function in future. Alternatively, <code>method</code> can be a list of functions named <code>init</code> , <code>split</code> and <code>eval</code> . Examples are given in the file 'tests/usersplits.R' in the sources, and in the vignettes 'User Written Split Functions'.
<code>model</code>	if logical: keep a copy of the model frame in the result? If the input value for <code>model</code> is a model frame (likely from an earlier call to the <code>rpart</code> function), then this frame is used rather than constructing new data.
<code>x</code>	keep a copy of the <code>x</code> matrix in the result.
<code>y</code>	keep a copy of the dependent variable in the result. If missing and <code>model</code> is supplied this defaults to <code>FALSE</code> .
<code>parms</code>	optional parameters for the splitting function. Anova splitting has no parameters. Poisson splitting has a single parameter, the coefficient of variation of the prior distribution on the rates. The default value is 1. Exponential splitting has the same parameter as Poisson. For classification splitting, the list can contain any of: the vector of prior probabilities (component <code>prior</code> ), the loss matrix (component <code>loss</code> ) or the splitting index (component <code>split</code> ). The priors must be positive and sum to 1. The loss matrix must have zeros on the diagonal and positive off-diagonal elements. The splitting index can be <code>gini</code> or <code>information</code> . The default priors are proportional to the data counts, the losses default to 1, and the split defaults to <code>gini</code> .
<code>control</code>	a list of options that control details of the <code>rpart</code> algorithm. See <a href="#">rpart.control</a> .
<code>cost</code>	a vector of non-negative costs, one for each variable in the model. Defaults to one for all variables. These are scalings to be applied when considering splits, so the improvement on splitting on a variable is divided by its cost in deciding which split to choose.
<code>...</code>	arguments to <a href="#">rpart.control</a> may also be specified in the call to <code>rpart</code> . They are checked against the list of valid arguments.

## Details

This differs from the `tree` function in S mainly in its handling of surrogate variables. In most details it follows Breiman *et. al* (1984) quite closely. R package **tree** provides a re-implementation of `tree`.

## Value

An object of class `rpart`. See [rpart.object](#).

## References

Breiman L., Friedman J. H., Olshen R. A., and Stone, C. J. (1984) *Classification and Regression Trees*. Wadsworth.

**Examples**

```
fit <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis)
fit2 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
             parms = list(prior = c(.65,.35), split = "information"))
fit3 <- rpart(Kyphosis ~ Age + Number + Start, data = kyphosis,
             control = rpart.control(cp = 0.05))
par(mfrow = c(1,2), xpd = NA) # otherwise on some devices the text is clipped
plot(fit)
text(fit, use.n = TRUE)
plot(fit2)
text(fit2, use.n = TRUE)
```

---

rpart.control

*Control for Rpart Fits*

---

**Description**

Various parameters that control aspects of the rpart fit.

**Usage**

```
rpart.control(minsplit = 20, minbucket = round(minsplit/3), cp = 0.01,
             maxcompete = 4, maxsurrogate = 5, usesurrogate = 2, xval = 10,
             surrogatestyle = 0, maxdepth = 30, ...)
```

**Arguments**

minsplit	the minimum number of observations that must exist in a node in order for a split to be attempted.
minbucket	the minimum number of observations in any terminal <code>&lt;leaf&gt;</code> node. If only one of minbucket or minsplit is specified, the code either sets minsplit to minbucket*3 or minbucket to minsplit/3, as appropriate.
cp	complexity parameter. Any split that does not decrease the overall lack of fit by a factor of cp is not attempted. For instance, with anova splitting, this means that the overall R-squared must increase by cp at each step. The main role of this parameter is to save computing time by pruning off splits that are obviously not worthwhile. Essentially, the user informs the program that any split which does not improve the fit by cp will likely be pruned off by cross-validation, and that hence the program need not pursue it.
maxcompete	the number of competitor splits retained in the output. It is useful to know not just which split was chosen, but which variable came in second, third, etc.
maxsurrogate	the number of surrogate splits retained in the output. If this is set to zero the compute time will be reduced, since approximately half of the computational time (other than setup) is used in the search for surrogate splits.

usesurrogate	how to use surrogates in the splitting process. 0 means display only; an observation with a missing value for the primary split rule is not sent further down the tree. 1 means use surrogates, in order, to split subjects missing the primary variable; if all surrogates are missing the observation is not split. For value 2, if all surrogates are missing, then send the observation in the majority direction. A value of 0 corresponds to the action of <code>tree</code> , and 2 to the recommendations of Breiman <i>et.al</i> (1984).
xval	number of cross-validations.
surrogatestyle	controls the selection of a best surrogate. If set to 0 (default) the program uses the total number of correct classification for a potential surrogate variable, if set to 1 it uses the percent correct, calculated over the non-missing values of the surrogate. The first option more severely penalizes covariates with a large number of missing values.
maxdepth	Set the maximum depth of any node of the final tree, with the root node counted as depth 0. Values greater than 30 <code>rpart</code> will give nonsense results on 32-bit machines.
...	mop up other arguments.

**Value**

A list containing the options.

**See Also**

[rpart](#)

---

`rpart.exp`

*Initialization function for exponential fitting*

---

**Description**

This function does the initialization step for `rpart`, when the response is a survival object. It rescales the data so as to have an exponential baseline hazard and then uses Poisson methods. This function would rarely if ever be called directly by a user.

**Usage**

```
rpart.exp(y, offset, parms, wt)
```

**Arguments**

<code>y</code>	the response, which will be of class <code>Surv</code>
<code>offset</code>	optional offset
<code>parms</code>	parameters controlling the fit. This is a list with components <code>shrink</code> and <code>method</code> . The first is the prior for the coefficient of variation of the predictions. The second is either "deviance" or "sqrt" and is the measure used for cross-validation. If values are missing the defaults are used, which are "deviance" for the method, and a shrinkage of 1.0 for the deviance method and 0 for the square root.
<code>wt</code>	case weights, if present

**Value**

a list with the necessary initialization components

**Author(s)**

Terry Therneau

[rpart](#)

---

rpart.object

Recursive Partitioning and Regression Trees Object

---

**Description**

These are objects representing fitted `rpart` trees.

**Value**

frame	data frame with one row for each node in the tree. The <code>row.names</code> of <code>frame</code> contain the (unique) node numbers that follow a binary ordering indexed by node depth. Columns of <code>frame</code> include <code>var</code> , a factor giving the names of the variables used in the split at each node (leaf nodes are denoted by the level " <code>&lt;leaf&gt;</code> "), <code>n</code> , the number of observations reaching the node, <code>wt</code> , the sum of case weights for observations reaching the node, <code>dev</code> , the deviance of the node, <code>yval</code> , the fitted value of the response at the node, and <code>splits</code> , a two column matrix of left and right split labels for each node. Also included in the frame are <code>complexity</code> , the complexity parameter at which this split will collapse, <code>ncompete</code> , the number of competitor splits recorded, and <code>nsurrogate</code> , the number of surrogate splits recorded.  Extra response information which may be present is in <code>yval2</code> , which contains the number of events at the node (poisson tree), or a matrix containing the fitted class, the class counts for each node, the class probabilities and the 'node probability' (classification trees).
where	an integer vector of the same length as the number of observations in the root node, containing the row number of <code>frame</code> corresponding to the leaf node that each observation falls into.
call	an image of the call that produced the object, but with the arguments all named and with the actual formula included as the formula argument. To re-evaluate the call, say <code>update(tree)</code> .
terms	an object of class <code>c("terms", "formula")</code> (see <a href="#">terms.object</a> ) summarizing the formula. Used by various methods, but typically not of direct relevance to users.
splits	a numeric matrix describing the splits: only present if there are any. The row label is the name of the split variable, and columns are <code>count</code> , the number of observations (which are not missing and are of positive weight) sent left or right by the split (for competitor splits this is the number that would have been sent left or right had this split been used, for surrogate splits it is the number missing

the primary split variable which were decided using this surrogate), `ncat`, the number of categories or levels for the variable ( $+/-1$  for a continuous variable), `improve`, which is the improvement in deviance given by this split, or, for surrogates, the concordance of the surrogate with the primary, and `index`, the numeric split point. The last column `adj` gives the adjusted concordance for surrogate splits. For a factor, the `index` column contains the row number of the `csplit` matrix. For a continuous variable, the sign of `ncat` determines whether the subset  $x < \text{cutpoint}$  or  $x > \text{cutpoint}$  is sent to the left.

<code>csplit</code>	an integer matrix. (Only present only if at least one of the split variables is a factor or ordered factor.) There is a row for each such split, and the number of columns is the largest number of levels in the factors. Which row is given by the <code>index</code> column of the <code>splits</code> matrix. The columns record 1 if that level of the factor goes to the left, 3 if it goes to the right, and 2 if that level is not present at this node of the tree (or not defined for the factor).
<code>method</code>	character string: the method used to grow the tree. One of "class", "exp", "poisson", "anova" or "user" (if splitting functions were supplied).
<code>cptable</code>	a matrix of information on the optimal prunings based on a complexity parameter.
<code>variable.importance</code>	a named numeric vector giving the importance of each variable. (Only present if there are any splits.) When printed by <code>summary.rpart</code> these are rescaled to add to 100.
<code>numresp</code>	integer number of responses; the number of levels for a factor response.
<code>parms, control</code>	a record of the arguments supplied, which defaults filled in.
<code>functions</code>	the <code>summary</code> , <code>print</code> and <code>text</code> functions for method used.
<code>ordered</code>	a named logical vector recording for each variable if it was an ordered factor.
<code>na.action</code>	(where relevant) information returned by <code>model.frame</code> on the special handling of NAs derived from the <code>na.action</code> argument.

There may be `attributes` "xlevels" and "levels" recording the levels of any factor splitting variables and of a factor response respectively.

Optional components include the model frame (`model`), the matrix of predictors (`x`) and the response variable (`y`) used to construct the `rpart` object.

## Structure

The following components must be included in a legitimate `rpart` object.

## See Also

`rpart.`

rsq.rpart

*Plots the Approximate R-Square for the Different Splits***Description**

Produces 2 plots. The first plots the r-square (apparent and apparent - from cross-validation) versus the number of splits. The second plots the Relative Error(cross-validation) +/- 1-SE from cross-validation versus the number of splits.

**Usage**

```
rsq.rpart(x)
```

**Arguments**

**x** fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.

**Side Effects**

Two plots are produced.

**Note**

The labels are only appropriate for the "anova" method.

**Examples**

```
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
rsq.rpart(z.auto)
```

snip.rpart

*Snip Subtrees of an Rpart Object***Description**

Creates a "snipped" rpart object, containing the nodes that remain after selected subtrees have been snipped off. The user can snip nodes using the `toss` argument, or interactively by clicking the mouse button on specified nodes within the graphics window.

**Usage**

```
snip.rpart(x, toss)
```

**Arguments**

**x** fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the `rpart` function.

**toss** an integer vector containing indices (node numbers) of all subtrees to be snipped off. If missing, user selects branches to snip off as described below.

### Details

A dendrogram of `rpart` is expected to be visible on the graphics device, and a graphics input device (e.g., a mouse) is required. Clicking (the selection button) on a node displays the node number, sample size, response y-value, and Error (dev). Clicking a second time on the same node snips that subtree off and visually erases the subtree. This process may be repeated an number of times. Warnings result from selecting the root or leaf nodes. Clicking the exit button will stop the snipping process and return the resulting `rpart` object.

See the documentation for the specific graphics device for details on graphical input techniques.

### Value

A `rpart` object containing the nodes that remain after specified or selected subtrees have been snipped off.

### Warning

Visually erasing the plot is done by over-plotting with the background colour. This will do nothing if the background is transparent (often true for screen devices).

### See Also

`plot.rpart`

### Examples

```
## dataset not in R
## Not run:
z.survey <- rpart(market.survey) # grow the rpart object
plot(z.survey) # plot the tree
z.survey2 <- snip.rpart(z.survey, toss = 2) # trim subtree at node 2
plot(z.survey2) # plot new tree

# can also interactively select the node using the mouse in the
# graphics window

## End(Not run)
```

---

solder

*Soldering of Components on Printed-Circuit Boards*

---

### Description

The `solder` data frame has 720 rows and 6 columns, representing a balanced subset of a designed experiment varying 5 factors on the soldering of components on printed-circuit boards.

### Usage

`solder`

**Format**

This data frame contains the following columns:

Opening a factor with levels 'L', 'M' and 'S' indicating the amount of clearance around the mounting pad.

Solder a factor with levels 'Thick' and 'Thin' giving the thickness of the solder used.

Mask a factor with levels 'A1.5', 'A3', 'B3' and 'B6' indicating the type and thickness of mask used.

PadType a factor with levels 'D4', 'D6', 'D7', 'L4', 'L6', 'L7', 'L8', 'L9', 'W4' and 'W9' giving the size and geometry of the mounting pad.

Panel 1:3 indicating the panel on a board being tested.

skips a numeric vector giving the number of visible solder skips.

**Source**

John M. Chambers and Trevor J. Hastie eds. (1992) *Statistical Models in S*, Wadsworth and Brooks/Cole, Pacific Grove, CA.

**Examples**

```
fit <- rpart(skips ~ Opening + Solder + Mask + PadType + Panel,
            data = solder, method = "anova")
summary(residuals(fit))
plot(predict(fit), residuals(fit))
```

---

stagec

*Stage C Prostate Cancer*

---

**Description**

A set of 146 patients with stage C prostate cancer, from a study exploring the prognostic value of flow cytometry.

**Usage**

```
data(stagec)
```

**Format**

A data frame with 146 observations on the following 8 variables.

pgtime Time to progression or last follow-up (years)

pgstat 1 = progression observed, 0 = censored

age age in years

eet early endocrine therapy, 1 = no, 2 = yes

g2 percent of cells in G2 phase, as found by flow cytometry

grade grade of the tumor, Farrow system

gleason grade of the tumor, Gleason system

ploidy the ploidy status of the tumor, from flow cytometry. Values are 'diploid', 'tetraploid', and 'aneuploid'

## Details

A tumor is called diploid (normal complement of dividing cells) if the fraction of cells in G2 phase was determined to be 13% or less. Aneuploid cells have a measurable fraction with a chromosome count that is neither 24 nor 48, for these the G2 percent is difficult or impossible to measure.

## Examples

```
require(survival)
rpart(Surv(pptime, pgstat) ~ ., stagec)
```

---

summary.rpart

*Summarize a Fitted Rpart Object*

---

## Description

Returns a detailed listing of a fitted rpart object.

## Usage

```
## S3 method for class 'rpart'
summary(object, cp = 0, digits = getOption("digits"), file, ...)
```

## Arguments

object	fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the rpart function.
digits	Number of significant digits to be used in the result.
cp	trim nodes with a complexity of less than cp from the listing.
file	write the output to a given file name. (Full listings of a tree are often quite long).
...	arguments to be passed to or from other methods.

## Details

This function is a method for the generic function summary for class "rpart". It can be invoked by calling summary for an object of the appropriate class, or directly by calling summary.rpart regardless of the class of the object.

It prints the call, the table shown by printcp, the variable importance (summing to 100) and details for each node (the details depending on the type of tree).

## See Also

[summary](#), [rpart.object](#), [printcp](#).

## Examples

```
## a regression tree
z.auto <- rpart(Mileage ~ Weight, car.test.frame)
summary(z.auto)

## a classification tree with multiple variables and surrogate splits.
summary(rpart(Kyphosis ~ Age + Number + Start, data = kyphosis))
```

text.rpart

*Place Text on a Dendrogram Plot***Description**

Labels the current plot of the tree dendrogram with text.

**Usage**

```
## S3 method for class 'rpart'
text(x, splits = TRUE, label, FUN = text, all = FALSE,
     pretty = NULL, digits = getOption("digits") - 3, use.n = FALSE,
     fancy = FALSE, fwidth = 0.8, fheight = 0.8, bg = par("bg"),
     minlength = 1L, ...)
```

**Arguments**

x	fitted model object of class "rpart". This is assumed to be the result of some function that produces an object with the same named components as that returned by the <code>rpart</code> function.
splits	logical flag. If <code>TRUE</code> (default), then the splits in the tree are labeled with the criterion for the split.
label	For compatibility with <code>rpart2</code> , ignored in this version (with a warning).
FUN	the name of a labeling function, e.g. <code>text</code> .
all	Logical. If <code>TRUE</code> , all nodes are labeled, otherwise just terminal nodes.
minlength	the length to use for factor labels. A value of 1 causes them to be printed as 'a', 'b', .... Larger values use abbreviations of the label names. See the <code>labels.rpart</code> function for details.
pretty	an alternative to the <code>minlength</code> argument, see <a href="#">labels.rpart</a> .
digits	number of significant digits to include in numerical labels.
use.n	Logical. If <code>TRUE</code> , adds to label <code>(\#events level1/\#events level2/etc. for class, n for anova, and \#events/n for poisson and exp)</code> .
fancy	Logical. If <code>TRUE</code> , nodes are represented by ellipses (interior nodes) and rectangles (leaves) and labeled by <code>yval</code> . The edges connecting the nodes are labeled by left and right splits.
fwidth	Relates to option <code>fancy</code> and the width of the ellipses and rectangles. If <code>fwidth &lt; 1</code> then it is a scaling factor (default = 0.8). If <code>fwidth &gt; 1</code> then it represents the number of character widths (for current graphical device) to use.
fheight	Relates to option <code>fancy</code> and the height of the ellipses and rectangles. If <code>fheight &lt; 1</code> then it is a scaling factor (default = 0.8). If <code>fheight &gt; 1</code> then it represents the number of character heights (for current graphical device) to use.
bg	The color used to paint the background to annotations if <code>fancy = TRUE</code> .
...	Graphical parameters may also be supplied as arguments to this function (see <code>par</code> ). As labels often extend outside the plot region it can be helpful to specify <code>xpd = TRUE</code> .

**Side Effects**

the current plot of a tree dendrogram is labeled.

**See Also**

`text`, `plot.rpart`, `rpart`, `labels.rpart`, `abbreviate`

**Examples**

```
freen.tr <- rpart(y ~ ., freeny)
par(xpd = TRUE)
plot(freen.tr)
text(freen.tr, use.n = TRUE, all = TRUE)
```

---

xpred.rpart

*Return Cross-Validated Predictions*

---

**Description**

Gives the predicted values for an `rpart` fit, under cross validation, for a set of complexity parameter values.

**Usage**

```
xpred.rpart(fit, xval = 10, cp, return.all = FALSE)
```

**Arguments**

<code>fit</code>	a object of class "rpart".
<code>xval</code>	number of cross-validation groups. This may also be an explicit list of integers that define the cross-validation groups.
<code>cp</code>	the desired list of complexity values. By default it is taken from the <code>cp</code> table component of the fit.
<code>return.all</code>	if FALSE return only the first element of the prediction

**Details**

Complexity penalties are actually ranges, not values. If the `cp` values found in the table were .36, .28, and .13, for instance, this means that the first row of the table holds for all complexity penalties in the range [.36, 1], the second row for `cp` in the range [.28, .36) and the third row for [.13, .28). By default, the geometric mean of each interval is used for cross validation.

**Value**

A matrix with one row for each observation and one column for each complexity value. If `return.all` is TRUE and the prediction for each node is a vector, then the result will be an array containing all of the predictions. When the response is categorical, for instance, the result contains the predicted class followed by the class probabilities of the selected terminal node; `result[1, , ]` will be the matrix of predicted classes, `result[2, , ]` the matrix of class 1 probabilities, etc.

**See Also**[rpart](#)**Examples**

```
fit <- rpart(Mileage ~ Weight, car.test.frame)
xmat <- xpred.rpart(fit)
xerr <- (xmat - car.test.frame$Mileage)^2
apply(xerr, 2, sum)    # cross-validated error estimate

# approx same result as rel. error from printcp(fit)
apply(xerr, 2, sum)/var(car.test.frame$Mileage)
printcp(fit)
```

## Chapter 28

# The `spatial` package

---

`anova.trls`

*Anova tables for fitted trend surface objects*

---

### Description

Compute analysis of variance tables for one or more fitted trend surface model objects; where `anova.trls` is called with multiple objects, it passes on the arguments to `anovalist.trls`.

### Usage

```
## S3 method for class 'trls'
anova(object, ...)
anovalist.trls(object, ...)
```

### Arguments

<code>object</code>	A fitted trend surface model object from <code>surf.ls</code>
<code>...</code>	Further objects of the same kind

### Value

`anova.trls` and `anovalist.trls` return objects corresponding to their printed tabular output.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### See Also

**Examples**

```
library(stats)
data(topo, package="MASS")
topo0 <- surf.ls(0, topo)
topo1 <- surf.ls(1, topo)
topo2 <- surf.ls(2, topo)
topo3 <- surf.ls(3, topo)
topo4 <- surf.ls(4, topo)
anova(topo0, topo1, topo2, topo3, topo4)
summary(topo4)
```

---

correlogram	<i>Compute Spatial Correlograms</i>
-------------	-------------------------------------

---

**Description**

Compute spatial correlograms of spatial data or residuals.

**Usage**

```
correlogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

<code>krig</code>	trend-surface or kriging object with columns <code>x</code> , <code>y</code> , and <code>z</code>
<code>nint</code>	number of bins used
<code>plotit</code>	logical for plotting
<code>...</code>	parameters for the plot

**Details**

Divides range of data into `nint` bins, and computes the covariance for pairs with separation in each bin, then divides by the variance. Returns results for bins with 6 or more pairs.

**Value**

`x` and `y` coordinates of the correlogram, and `cnt`, the number of pairs averaged per bin.

**Side Effects**

Plots the correlogram if `plotit = TRUE`.

**References**

**Examples**

```
data(topo, package="MASS")
topo.kr <- surf.ls(2, topo)
correlogram(topo.kr, 25)
d <- seq(0, 7, 0.1)
lines(d, expcov(d, 0.7))
```

---

expcov

*Spatial Covariance Functions*

---

**Description**

Spatial covariance functions for use with `surf.gls`.

**Usage**

```
expcov(r, d, alpha = 0, se = 1)
gaucov(r, d, alpha = 0, se = 1)
sphercov(r, d, alpha = 0, se = 1, D = 2)
```

**Arguments**

<code>r</code>	vector of distances at which to evaluate the covariance
<code>d</code>	range parameter
<code>alpha</code>	proportion of nugget effect
<code>se</code>	standard deviation at distance zero
<code>D</code>	dimension of spheres.

**Value**

vector of covariance values.

```

---

Kaver

Average *K*-functions from Simulations

---

## Description

Forms the average of a series of (usually simulated) *K*-functions.

## Usage

```
Kaver(fs, nsim, ...)
```

## Arguments

<code>fs</code>	full scale for <i>K</i> -fn
<code>nsim</code>	number of simulations
<code>...</code>	arguments to simulate one point process object

## Value

list with components `x` and `y` of the average *K*-fn on L-scale.

## References

Ripley, B. D. (1981) *Spatial Statistics*. Wiley.

```

Kenvl

*Compute Envelope and Average of Simulations of K-fns***Description**

Computes envelope (upper and lower limits) and average of simulations of K-fns

**Usage**

```
Kenvl(fs, nsim, ...)
```

**Arguments**

fs	full scale for K-fn
nsim	number of simulations
...	arguments to produce one simulation

**Value**

list with components

x	distances
lower	min of K-fns
upper	max of K-fns
aver	average of K-fns

**References**

```

Kfn

*Compute K-fn of a Point Pattern***Description**

Actually computes  $L = \sqrt{K/\pi}$ .

**Usage**

```
Kfn(pp, fs, k=100)
```

**Arguments**

pp	a list such as a pp object, including components <code>x</code> and <code>y</code>
fs	full scale of the plot
k	number of regularly spaced distances in (0, fs)

**Details**

relies on the domain D having been set by `ppinit` or `ppregion`.

**Value**

A list with components

x	vector of distances
y	vector of L-fn values
k	number of distances returned – may be less than k if fs is too large
dmin	minimum distance between pair of points
lm	maximum deviation from $L(t) = t$

ppinit

*Read a Point Process Object from a File***Description**

Read a file in standard format and create a point process object.

**Usage**

```
ppinit(file)
```

**Arguments**

`file`                      string giving file name

**Details**

The file should contain  
the number of points  
a header (ignored)  
`xl xu yl yu scale`  
`x y` (repeated `n` times)

**Value**

class "pp" object with components `x`, `y`, `xl`, `xu`, `yl`, `yu`

**Side Effects**

Calls `ppregion` to set the domain.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

---

pplik

*Pseudo-likelihood Estimation of a Strauss Spatial Point Process*

---

**Description**

Pseudo-likelihood estimation of a Strauss spatial point process.

**Usage**

```
pplik(pp, R, ng=50, trace=FALSE)
```

**Arguments**

<code>pp</code>	a <code>pp</code> object
<code>R</code>	the fixed parameter <code>R</code>
<code>ng</code>	use a <code>ng</code> x <code>ng</code> grid with border <code>R</code> in the domain for numerical integration.
<code>trace</code>	logical? Should function evaluations be printed?

**Value**

estimate for  $c$  in the interval  $[0, 1]$ .

**References**

```

---

ppregion

---

Set Domain for Spatial Point Pattern Analyses

---

**Description**

Sets the rectangular domain  $(x_l, x_u) \times (y_l, y_u)$ .

**Usage**

```
ppregion(xl = 0, xu = 1, yl = 0, yu = 1)
```

**Arguments**

`xl` Either `xl` or a list containing components `xl`, `xu`, `yl`, `yu` (such as a point-process object)

`xu`

`yl`

`yu`

**Value**

none

**Side Effects**

initializes variables in the C subroutines.

predict.trls

---

Predict method for trend surface fits

---

**Description**

Predicted values based on trend surface model object

**Usage**

```
## S3 method for class 'trls'
predict(object, x, y, ...)
```

Arguments

object	Fitted trend surface model object returned by <code>surf.ls</code>
x	Vector of prediction location eastings (x coordinates)
y	Vector of prediction location northings (y coordinates)
...	further arguments passed to or from other methods.

Value

`predict.trls` produces a vector of predictions corresponding to the prediction locations. To display the output with `image` or `contour`, use `trmat` or convert the returned vector to matrix form.

References

```

---

prmat	<i>Evaluate Kriging Surface over a Grid</i>
-------	---

---

Description

Evaluate Kriging surface over a grid.

Usage

```
prmat(obj, xl, xu, yl, yu, n)
```

Arguments

obj	object returned by <code>surf.gls</code>
xl	limits of the rectangle for grid
xu	
yl	
yu	
n	use $n \times n$ grid within the rectangle

**Value**

list with components `x`, `y` and `z` suitable for `contour` and `image`.

```

---

Psim

*Simulate Binomial Spatial Point Process*

---

**Description**

Simulate Binomial spatial point process.

**Usage**

```
Psim(n)
```

**Arguments**

`n`                      number of points

**Details**

relies on the region being set by `ppinit` or `ppregion`.

**Value**

list of vectors of `x` and `y` coordinates.

**Side Effects**

uses the random number generator.

**References**

---

semat

*Evaluate Kriging Standard Error of Prediction over a Grid*

---

**Description**

Evaluate Kriging standard error of prediction over a grid.

**Usage**

```
semat(obj, xl, xu, yl, yu, n, se)
```

**Arguments**

obj	object returned by <code>surf.gls</code>
xl	limits of the rectangle for grid
xu	
yl	
yu	
n	use $n \times n$ grid within the rectangle
se	standard error at distance zero as a multiple of the supplied covariance. Otherwise estimated, and it assumed that a correlation function was supplied.

**Value**

list with components x, y and z suitable for `contour` and `image`.

contour(sesurf, levels=c(22,25))
```

---

SSI

*Simulates Sequential Spatial Inhibition Point Process*

---

**Description**

Simulates SSI (sequential spatial inhibition) point process.

**Usage**

```
SSI(n, r)
```

**Arguments**

n	number of points
r	inhibition distance

**Details**

uses the region set by `ppinit` or `ppregion`.

**Value**

list of vectors of  $x$  and  $y$  coordinates

**Side Effects**

uses the random number generator.

**Warnings**

will never return if  $r$  is too large and it cannot place  $n$  points.

**References**

```

Strauss

*Simulates Strauss Spatial Point Process***Description**

Simulates Strauss spatial point process.

**Usage**

```
Strauss(n, c=0, r)
```

**Arguments**

<code>n</code>	number of points
<code>c</code>	parameter $c$ in $[0, 1]$ . $c = 0$ corresponds to complete inhibition at distances up to $r$ .
<code>r</code>	inhibition distance

**Details**

Uses spatial birth-and-death process for  $4n$  steps, or for  $40n$  steps starting from a binomial pattern on the first call from an other function. Uses the region set by `ppinit` or `ppregion`.

**Value**

list of vectors of  $x$  and  $y$  coordinates

**Side Effects**

uses the random number generator

surf.gls

*Fits a Trend Surface by Generalized Least-squares***Description**

Fits a trend surface by generalized least-squares.

**Usage**

```
surf.gls(np, covmod, x, y, z, nx = 1000, ...)
```

**Arguments**

np	degree of polynomial surface
covmod	function to evaluate covariance or correlation function
x	x coordinates or a data frame with columns x, y, z
y	y coordinates
z	z coordinates. Will supersede x\$z
nx	Number of bins for table of the covariance. Increasing adds accuracy, and increases size of the object.
...	parameters for covmod

**Value**

list with components

beta	the coefficients
x	
y	
z	and others for internal use only.

---

trls.influence	<i>Regression diagnostics for trend surfaces</i>
----------------	--

---

## Description

This function provides the basic quantities which are used in forming a variety of diagnostics for checking the quality of regression fits for trend surfaces calculated by `surf.ls`.

## Usage

```
trls.influence(object)
## S3 method for class 'trls'
plot(x, border = "red", col = NA, pch = 4, cex = 0.6,
      add = FALSE, div = 8, ...)
```

## Arguments

<code>object, x</code>	Fitted trend surface model from <code>surf.ls</code>
<code>div</code>	scaling factor for influence circle radii in <code>plot.trls</code>
<code>add</code>	add influence plot to existing graphics if TRUE
<code>border, col, pch, cex, ...</code>	additional graphical parameters

## Value

`trls.influence` returns a list with components:

<code>r</code>	raw residuals as given by <code>residuals.trls</code>
<code>hii</code>	diagonal elements of the Hat matrix
<code>stresid</code>	standardised residuals
<code>Di</code>	Cook's statistic

variogram

*Compute Spatial Variogram***Description**

Compute spatial (semi-)variogram of spatial data or residuals.

**Usage**

```
variogram(krig, nint, plotit = TRUE, ...)
```

**Arguments**

<code>krig</code>	trend-surface or kriging object with columns <code>x</code> , <code>y</code> , and <code>z</code>
<code>nint</code>	number of bins used
<code>plotit</code>	logical for plotting
<code>...</code>	parameters for the plot

**Details**

Divides range of data into `nint` bins, and computes the average squared difference for pairs with separation in each bin. Returns results for bins with 6 or more pairs.

**Value**

`x` and `y` coordinates of the variogram and `cnt`, the number of pairs averaged per bin.

**Side Effects**

Plots the variogram if `plotit = TRUE`

## Chapter 29

# The survival package

---

aareg

*Aalen's additive regression model for censored data*

---

### Description

Returns an object of class "aareg" that represents an Aalen model.

### Usage

```
aareg(formula, data, weights, subset, na.action,
      qrtol=1e-07, nmin, dfbeta=FALSE, taper=1,
      test = c('aalen', 'variance', 'nrisk'),
      model=FALSE, x=FALSE, y=FALSE)
```

### Arguments

formula	a formula object, with the response on the left of a '~' operator and the terms, separated by + operators, on the right. The response must be a <code>Surv</code> object. Due to a particular computational approach that is used, the model <b>MUST</b> include an intercept term. If "-1" is used in the model formula the program will ignore it.
data	data frame in which to interpret the variables named in the <code>formula</code> , <code>subset</code> , and <code>weights</code> arguments. This may also be a single number to handle some special cases – see below for details. If <code>data</code> is missing, the variables in the model formula should be in the search path.
weights	vector of observation weights. If supplied, the fitting algorithm minimizes the sum of the weights multiplied by the squared residuals (see below for additional technical details). The length of <code>weights</code> must be the same as the number of observations. The weights must be nonnegative and it is recommended that they be strictly positive, since zero weights are ambiguous. To exclude particular observations from the model, use the <code>subset</code> argument instead of zero weights.
subset	expression specifying which subset of observations should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating the observation numbers to be included, or a character vector of the observation names that should be included. All observations are included by default.

<code>na.action</code>	a function to filter missing data. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been applied. The default is <code>na.fail</code> , which returns an error if any missing values are found. An alternative is <code>na.exclude</code> , which deletes observations that contain one or more missing values.
<code>qrtol</code>	tolerance for detection of singularity in the QR decomposition
<code>nmin</code>	minimum number of observations for an estimate; defaults to 3 times the number of covariates. This essentially truncates the computations near the tail of the data set, when <code>n</code> is small and the calculations can become numerically unstable.
<code>dfbeta</code>	should the array of <code>dfbeta</code> residuals be computed. This implies computation of the sandwich variance estimate. The residuals will always be computed if there is a <code>cluster</code> term in the model formula.
<code>taper</code>	allows for a smoothed variance estimate. $\text{Var}(x)$ , where <code>x</code> is the set of covariates, is an important component of the calculations for the Aalen regression model. At any given time point <code>t</code> , it is computed over all subjects who are still at risk at time <code>t</code> . The <code>taper</code> argument allows smoothing these estimates, for example <code>taper=(1:4)/4</code> would cause the variance estimate used at any event time to be a weighted average of the estimated variance matrices at the last 4 death times, with a weight of 1 for the current death time and decreasing to 1/4 for prior event times. The default value gives the standard Aalen model.
<code>test</code>	selects the weighting to be used, for computing an overall “average” coefficient vector over time and the subsequent test for equality to zero.
<code>model, x, y</code>	should copies of the model frame, the <code>x</code> matrix of predictors, or the response vector <code>y</code> be included in the saved result.

## Details

The Aalen model assumes that the cumulative hazard  $H(t)$  for a subject can be expressed as  $a(t) + X B(t)$ , where  $a(t)$  is a time-dependent intercept term,  $X$  is the vector of covariates for the subject (possibly time-dependent), and  $B(t)$  is a time-dependent matrix of coefficients. The estimates are inherently non-parametric; a fit of the model will normally be followed by one or more plots of the estimates.

The estimates may become unstable near the tail of a data set, since the increment to  $B$  at time `t` is based on the subjects still at risk at time `t`. The tolerance and/or `nmin` parameters may act to truncate the estimate before the last death. The `taper` argument can also be used to smooth out the tail of the curve. In practice, the addition of a taper such as 1:10 appears to have little effect on death times when `n` is still reasonably large, but can considerably dampen wild oscillations in the tail of the plot.

## Value

an object of class "aareg" representing the fit, with the following components:

<code>n</code>	vector containing the number of observations in the data set, the number of event times, and the number of event times used in the computation
<code>times</code>	vector of sorted event times, which may contain duplicates
<code>nrisk</code>	vector containing the number of subjects at risk, of the same length as <code>times</code>
<code>coefficient</code>	matrix of coefficients, with one row per event and one column per covariate
<code>test.statistic</code>	the value of the test statistic, a vector with one element per covariate
<code>test.var</code>	variance-covariance matrix for the test

test	the type of test; a copy of the test argument above
tweight	matrix of weights used in the computation, one row per event
call	a copy of the call that produced this result

---

agreg.fit

---

*Cox model fitting functions*

---

## Description

These are the the functions called by `coxph` that do the actual computation. In certain situations, e.g. a simulation, it may be advantageous to call these directly rather than the usual `coxph` call using a model formula.

## Usage

```

agreg.fit(x, y, strata, offset, init, control, weights, method, rownames)
coxph.fit(x, y, strata, offset, init, control, weights, method, rownames)

```

## Arguments

<code>x</code>	Matix of predictors. This should <i>not</i> include an intercept.
<code>y</code>	a <code>Surv</code> object containing either 2 columns ( <code>coxph.fit</code> ) or 3 columns ( <code>agreg.fit</code> ).
<code>strata</code>	a vector containing the stratification, or <code>NULL</code>
<code>offset</code>	optional offset vector
<code>init</code>	initial values for the coefficients
<code>control</code>	the result of a call to <code>coxph.control</code>
<code>weights</code>	optional vector of weights
<code>method</code>	method for hanling ties, one of "breslow" or "efron"
<code>rownames</code>	this is only needed for a <code>NULL</code> model, in which case it contains the rownames (if any) of the original data.

## Details

This routine does no checking that arguments are the proper length or type. Only use it if you know what you are doing!

## Value

a list containing results of the fit

## Author(s)

Terry Therneau

aml	<i>Acute Myelogenous Leukemia survival data</i>
-----	---

---

**Description**

Survival in patients with Acute Myelogenous Leukemia. The question at the time was whether the standard course of chemotherapy should be extended ('maintainance') for additional cycles.

**Usage**

aml  
leukemia

**Format**

time: survival or censoring time  
status: censoring status  
x: maintenance chemotherapy given? (factor)

**Source**

Rupert G. Miller (1997), *Survival Analysis*. John Wiley & Sons. ISBN: 0-471-25218-2.

---

anova.coxph	<i>Analysis of Deviance for a Cox model.</i>
-------------	--

---

**Description**

Compute an analysis of deviance table for one or more Cox model fits.

**Usage**

```
## S3 method for class 'coxph'  
anova(object, ..., test = 'Chisq')
```

**Arguments**

object	An object of class coxph
...	Further coxph objects
test	a character string. The appropriate test is a chisquare, all other choices result in no test being done.

## Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the model log-likelihood as each term of the formula is added in turn are given in as the rows of a table, plus the log-likelihoods themselves. A robust variance estimate is normally used in situations where the model may be mis-specified, e.g., multiple events per subject. In this case a comparison of partial-likelihood values does not make sense, and `anova` will refuse to print results.

If more than one object is specified, the table has a row for the degrees of freedom and loglikelihood for each model. For all but the first model, the change in degrees of freedom and loglik is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in loglik for each row.

## Value

An object of class `"anova"` inheriting from class `"data.frame"`.

## Warning

The comparison between two or more models by `anova` or will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values.

## See Also

[coxph](#), [anova](#).

## Examples

```
fit <- coxph(Surv(futime, fustat) ~ resid.ds *rx + ecog.ps, data = ovarian)
anova(fit)
fit2 <- coxph(Surv(futime, fustat) ~ resid.ds +rx + ecog.ps, data=ovarian)
anova(fit2,fit)
```

---

attrassign

---

*Create new-style "assign" attribute*

---

## Description

The `"assign"` attribute on model matrices describes which columns come from which terms in the model formula. It has two versions. R uses the original version, but the alternate version found in S-plus is sometimes useful.

## Usage

```
## Default S3 method:
attrassign(object, tt,...)
## S3 method for class 'lm'
attrassign(object,...)
```

**Arguments**

<code>object</code>	model matrix or linear model object
<code>tt</code>	terms object
<code>...</code>	ignored

**Details**

For instance consider the following

```
survreg(Surv(time, status) ~ age + sex + factor(ph.ecog), lung)
```

R gives the compact for for assign, a vector (0, 1, 2, 3, 3, 3); which can be read as “the first column of the X matrix (intercept) goes with none of the terms, the second column of X goes with term 1 of the model equation, the third column of X with term 2, and columns 4-6 with term 3”.

The alternate (S-Plus default) form is a list

```
$(Intercept)      1
$age               2
$sex               3
$factor(ph.ecog)  4 5 6
```

**Value**

A list with names corresponding to the term names and elements that are vectors indicating which columns come from which terms

**See Also**

`terms`, `model.matrix`

**Examples**

```
formula <- Surv(time, status)~factor(ph.ecog)
tt <- terms(formula)
mf <- model.frame(tt, data=lung)
mm <- model.matrix(tt, mf)
## a few rows of data
mm[1:3,]
## old-style assign attribute
attr(mm, "assign")
## alternate style assign attribute
attrassign(mm, tt)
```

---

basehaz	<i>Alias for the survfit function</i>
---------	---------------------------------------

---

## Description

Compute the predicted survival curve for a Cox model.

## Usage

```
basehaz(fit, centered=TRUE)
```

## Arguments

<code>fit</code>	a coxph fit
<code>centered</code>	if TRUE return data from a predicted survival curve at the mean values of the covariates <code>fit\$mean</code> , if FALSE return a prediction for all covariates equal to zero.

## Details

This function is simply an alias for `survfit`, which is the actual function that does all the computations. See the manual page for that function for the preferred use. This function survives only for backwards support of prior usage.

The function returns a data frame containing the `time`, `cumhaz` and optionally the `strata` (if the fitted Cox model used a `strata` statement), which are copied the `survfit` result. If there are factor variables in the model, then the default predictions at the "mean" are meaningless since they do not correspond to any possible subject; correct results require use of the `newdata` argument of `survfit`. Results for all covariates =0 are normally only of use as a building block for further calculations.

## Value

a data frame with variable names of `hazard`, `time` and optionally `strata`. The first is actually the cumulative hazard.

## See Also

---

bladder	<i>Bladder Cancer Recurrences</i>
---------	-----------------------------------

---

## Description

Data on recurrences of bladder cancer, used by many people to demonstrate methodology for recurrent event modelling.

Bladder1 is the full data set from the study. It contains all three treatment arms and all recurrences for 118 subjects; the maximum observed number of recurrences is 9.

Bladder is the data set that appears most commonly in the literature. It uses only the 85 subjects with nonzero follow-up who were assigned to either thiotepa or placebo, and only the first four recurrences for any patient. The status variable is 1 for recurrence and 0 for everything else (including death for any reason). The data set is laid out in the competing risks format of the paper by Wei, Lin, and Weissfeld.

Bladder2 uses the same subset of subjects as bladder, but formatted in the (start, stop] or Anderson-Gill style. Note that in transforming from the WLW to the AG style data set there is a quite common programming mistake that leads to extra follow-up time for 12 subjects: all those with follow-up beyond their 4th recurrence). Over this extended time these subjects are by definition not at risk for another event in the WLW data set.

## Usage

```
bladder1
bladder
bladder2
```

## Format

bladder1

id:	Patient id
treatment:	Placebo, pyridoxine (vitamin B6), or thiotepa
number:	Initial number of tumours (8=8 or more)
size:	Size (cm) of largest initial tumour
recur:	Number of recurrences
start,stop:	The start and end time of each time interval
status:	End of interval code, 0=censored, 1=recurrence, 2=death from bladder disease, 3=death other/unknown cause
rtumor:	Number of tumors found at the time of a recurrence
rsize:	Size of largest tumor at a recurrence
enum:	Event number (observation number within patient)

bladder

id:	Patient id
rx:	Treatment 1=placebo 2=thiotepa
number:	Initial number of tumours (8=8 or more)
size:	size (cm) of largest initial tumour
stop:	recurrence or censoring time
enum:	which recurrence (up to 4)

bladder2

id:	Patient id
-----	------------

rx: Treatment 1=placebo 2=thiotepa  
 number: Initial number of tumours (8=8 or more)  
 size: size (cm) of largest initial tumour  
 start: start of interval (0 or previous recurrence time)  
 stop: recurrence or censoring time  
 enum: which recurrence (up to 4)

cch	<i>Fits proportional hazards regression model to case-cohort data</i>
-----	---

---

## Description

Returns estimates and standard errors from relative risk regression fit to data from case-cohort studies. A choice is available among the Prentice, Self-Prentice and Lin-Ying methods for unstratified data. For stratified data the choice is between Borgan I, a generalization of the Self-Prentice estimator for unstratified case-cohort data, and Borgan II, a generalization of the Lin-Ying estimator.

## Usage

```
cch(formula, data = sys.parent(), subcoh, id, stratum=NULL, cohort.size,
     method =c("Prentice", "SelfPrentice", "LinYing", "I.Borgan", "II.Borgan"),
     robust=FALSE)
```

## Arguments

formula	A formula object that must have a <a href="#">Surv</a> object as the response. The Surv object must be of type "right", or of type "counting".
subcoh	Vector of indicators for subjects sampled as part of the sub-cohort. Code 1 or TRUE for members of the sub-cohort, 0 or FALSE for others. If data is a data frame then subcoh may be a one-sided formula.
id	Vector of unique identifiers, or formula specifying such a vector.
stratum	A vector of stratum indicators or a formula specifying such a vector
cohort.size	Vector with size of each stratum original cohort from which subcohort was sampled
data	An optional data frame in which to interpret the variables occurring in the formula.
method	Three procedures are available. The default method is "Prentice", with options for "SelfPrentice" or "LinYing".
robust	For "LinYing" only, if robust=TRUE, use design-based standard errors even for phase I

## Details

Implements methods for case-cohort data analysis described by Therneau and Li (1999). The three methods differ in the choice of "risk sets" used to compare the covariate values of the failure with those of others at risk at the time of failure. "Prentice" uses the sub-cohort members "at risk" plus the failure if that occurs outside the sub-cohort and is score unbiased. "SelfPren" (Self-Prentice) uses just the sub-cohort members "at risk". These two have the same asymptotic variance-covariance matrix. "LinYing" (Lin-Ying) uses the all members of the sub-cohort and all failures outside the sub-cohort who are "at risk". The methods also differ in the weights given to different score contributions.

The `data` argument must not have missing values for any variables in the model. There must not be any censored observations outside the subcohort.

## Value

An object of class "cch" incorporating a list of estimated regression coefficients and two estimates of their asymptotic variance-covariance matrix.

<code>coef</code>	regression coefficients.
<code>naive.var</code>	Self-Prentice model based variance-covariance matrix.
<code>var</code>	Lin-Ying empirical variance-covariance matrix.

*Chronic Granulomatous Disease data*

---

## Description

Data are from a placebo controlled trial of gamma interferon in chronic granulomatous disease (CGD). Contains the data on time to serious infections observed through end of study for each patient.

## Usage

```
cgd
```

## Format

**id** subject identification number  
**center** enrolling center  
**random** date of randomization

**treatment** placebo or gamma interferon  
**sex** sex  
**age** age in years, at study entry  
**height** height in cm at study entry  
**weight** weight in kg at study entry  
**inherit** pattern of inheritance  
**steroids** use of steroids at study entry, 1=yes  
**propylac** use of prophylactic antibiotics at study entry  
**hos.cat** a categorization of the centers into 4 groups  
**tstart, tstop** start and end of each time interval  
**status** 1=the interval ends with an infection  
**enum** observation number within subject

### Details

The `cgd0` data set is in the form found in the references, with one line per patient and no recoding of the variables. The `cgd` data set (this one) has been cast into (start, stop] format with one line per event, and covariates such as center recoded as factors to include meaningful labels.

---

clogit	<i>Conditional logistic regression</i>
--------	--

---

Description

Estimates a logistic regression model by maximising the conditional likelihood. Uses a model formula of the form `case.status~exposure+strata(matched.set)`. The default is to use the exact conditional likelihood, a commonly used approximate conditional likelihood is provided for compatibility with older software.

Usage

```
clogit(formula, data, weights, subset, na.action,
        method=c("exact", "approximate", "efron", "breslow"),
        ...)
```

Arguments

<code>formula</code>	Model formula
<code>data</code>	data frame
<code>weights</code>	optional, names the variable containing case weights
<code>subset</code>	optional, subset the data
<code>na.action</code>	optional <code>na.action</code> argument. By default the global option <code>na.action</code> is used.
<code>method</code>	use the correct (exact) calculation in the conditional likelihood or one of the approximations
<code>...</code>	optional arguments, which will be passed to <code>coxph.control</code>

## Details

It turns out that the loglikelihood for a conditional logistic regression model = loglik from a Cox model with a particular data structure. Proving this is a nice homework exercise for a PhD statistics class; not too hard, but the fact that it is true is surprising.

When a well tested Cox model routine is available many packages use this ‘trick’ rather than writing a new software routine from scratch, and this is what the clogit routine does. In detail, a stratified Cox model with each case/control group assigned to its own stratum, time set to a constant, status of 1=case 0=control, and using the exact partial likelihood has the same likelihood formula as a conditional logistic regression. The clogit routine creates the necessary dummy variable of times (all 1) and the strata, then calls coxph.

The computation of the exact partial likelihood can be very slow, however. If a particular strata had say 10 events out of 20 subjects we have to add up a denominator that involves all possible ways of choosing 10 out of 20, which is  $20!/(10! \ 10!) = 184756$  terms. Gail et al describe a fast recursion method which partly ameliorates this; it was incorporated into version 2.36-11 of the survival package. The computation remains infeasible for very large groups of ties, say 100 ties out of 500 subjects, and may even lead to integer overflow for the subscripts – in this latter case the routine will refuse to undertake the task. The Efron approximation is normally a sufficiently accurate substitute.

Most of the time conditional logistic modeling is applied data with 1 case + k controls per set, however, in which case all of the approximations for ties lead to exactly the same result. The ‘approximate’ option maps to the Breslow approximation for the Cox model, for historical reasons.

It is not clear how case weights should be handled. For instance if there are two deaths in a strata, one with weight=1 and one with weight=2, should the likelihood calculation consider all subsets of size 2 or all subsets of size 3? Consequently, case weights are ignored by the routine.

## Value

An object of class "clogit", which is a wrapper for a "coxph" object.

logan2$case <- (logan2$occupation == logan2$tocc)
clogit(case ~ tocc + tocc:education + strata(id), logan2)

```

---

cluster

*Identify clusters.*

---

## Description

This is a special function used in the context of survival models. It identifies correlated groups of observations, and is used on the right hand side of a formula. Using `cluster()` in a formula implies that robust sandwich variance estimators are desired.

## Usage

```
cluster(x)
```

## Arguments

`x`                      A character, factor, or numeric variable.

## Details

The function's only action is semantic, to mark a variable as the cluster indicator. The resulting variance is what is known as the "working independence" variance in a GEE model. Note that one cannot use both a frailty term and a cluster term in the same model, the first is a mixed-effects approach to correlation and the second a GEE approach, and these don't mix.

## Value

`x`

## See Also

*Chemotherapy for Stage B/C colon cancer***Description**

These are data from one of the first successful trials of adjuvant chemotherapy for colon cancer. Levamisole is a low-toxicity compound previously used to treat worm infestations in animals; 5-FU is a moderately toxic (as these things go) chemotherapy agent. There are two records per person, one for recurrence and one for death

**Usage**

colon

**Format**

id: id  
 study: 1 for all patients  
 rx: Treatment - Obs(ervation), Lev(amisole), Lev(amisole)+5-FU  
 sex: 1=male  
 age: in years  
 obstruct: obstruction of colon by tumour  
 perfor: perforation of colon  
 adhere: adherence to nearby organs  
 nodes: number of lymph nodes with detectable cancer  
 time: days until event or censoring  
 status: censoring status  
 differ: differentiation of tumour (1=well, 2=moderate, 3=poor)  
 extent: Extent of local spread (1=submucosa, 2=muscle, 3=serosa, 4=contiguous structures)  
 surg: time from surgery to registration (0=short, 1=long)  
 node4: more than 4 positive lymph nodes  
 etype: event type: 1=recurrence,2=death

**Note**

The study is originally described in Laurie (1989). The main report is found in Moertel (1990). This data set is closest to that of the final report in Moertel (1991). A version of the data with less follow-up time was used in the paper by Lin (1994).

 cox.zph

---

*Test the Proportional Hazards Assumption of a Cox Regression*

---

## Description

Test the proportional hazards assumption for a Cox regression model fit (coxph).

## Usage

```
cox.zph(fit, transform="km", global=TRUE)
```

## Arguments

fit	the result of fitting a Cox regression model, using the coxph function.
transform	a character string specifying how the survival times should be transformed before the test is performed. Possible values are "km", "rank", "identity" or a function of one argument.
global	should a global chi-square test be done, in addition to the per-variable tests.

## Value

an object of class "cox.zph", with components:

table	a matrix with one row for each variable, and optionally a last row for the global test. Columns of the matrix contain the correlation coefficient between transformed survival time and the scaled Schoenfeld residuals, a chi-square, and the two-sided p-value. For the global test there is no appropriate correlation, so an NA is entered into the matrix as a placeholder.
x	the transformed time axis.
y	the matrix of scaled Schoenfeld residuals. There will be one column per variable and one row per event. The row labels contain the original event times (for the identity transform, these will be the same as x).
call	the calling sequence for the routine.  The computations require the original x matrix of the Cox model fit. Thus it saves time if the x=TRUE option is used in coxph. This function would usually be followed by both a plot and a print of the result. The plot gives an estimate of the time-dependent coefficient $\beta(t)$ . If the proportional hazards assumption is true, $\beta(t)$ will be a horizontal line. The printout gives a test for slope=0.

```

---

coxph	<i>Fit Proportional Hazards Regression Model</i>
-------	--

---

Description

Fits a Cox proportional hazards regression model. Time dependent variables, time dependent strata, multiple events per subject, and other extensions are incorporated using the counting process formulation of Andersen and Gill.

Usage

```
coxph(formula, data=, weights, subset,
       na.action, init, control,
       ties=c("efron", "breslow", "exact"),
       singular.ok=TRUE, robust=FALSE,
       model=FALSE, x=FALSE, y=TRUE, tt, method, ...)
```

Arguments

formula	a formula object, with the response on the left of a ~ operator, and the terms on the right. The response must be a survival object as returned by the <code>Surv</code> function.
data	a <code>data.frame</code> in which to interpret the variables named in the <code>formula</code> , or in the <code>subset</code> and the <code>weights</code> argument.
weights	vector of case weights. If <code>weights</code> is a vector of integers, then the estimated coefficients are equivalent to estimating the model from data with the individual cases replicated as many times as indicated by <code>weights</code> .
subset	expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.
na.action	a missing-data filter function. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
init	vector of initial values of the iteration. Default initial value is zero for all variables.

<code>control</code>	Object of class <code>coxph.control</code> specifying iteration limit and other control options. Default is <code>coxph.control(...)</code> .
<code>ties</code>	a character string specifying the method for tie handling. If there are no tied death times all the methods are equivalent. Nearly all Cox regression programs use the Breslow method by default, but not this one. The Efron approximation is used as the default here, it is more accurate when dealing with tied death times, and is as efficient computationally. The “exact partial likelihood” is equivalent to a conditional logistic model, and is appropriate when the times are a small set of discrete values. See further below.
<code>singular.ok</code>	logical value indicating how to handle collinearity in the model matrix. If <code>TRUE</code> , the program will automatically skip over columns of the X matrix that are linear combinations of earlier columns. In this case the coefficients for such columns will be NA, and the variance matrix will contain zeros. For ancillary calculations, such as the linear predictor, the missing coefficients are treated as zeros.
<code>robust</code>	this argument has been deprecated, use a cluster term in the model instead. (The two options accomplish the same goal – creation of a robust variance – but the second is more flexible).
<code>model</code>	logical value: if <code>TRUE</code> , the model frame is returned in component <code>model</code> .
<code>x</code>	logical value: if <code>TRUE</code> , the x matrix is returned in component <code>x</code> .
<code>y</code>	logical value: if <code>TRUE</code> , the response vector is returned in component <code>y</code> .
<code>tt</code>	optional list of time-transform functions.
<code>method</code>	alternate name for the <code>ties</code> argument.
<code>...</code>	Other arguments will be passed to <code>coxph.control</code>

### Details

The proportional hazards model is usually expressed in terms of a single survival time value for each person, with possible censoring. Andersen and Gill reformulated the same problem as a counting process; as time marches onward we observe the events for a subject, rather like watching a Geiger counter. The data for a subject is presented as multiple rows or "observations", each of which applies to an interval of observation (start, stop].

The routine internally scales and centers data to avoid overflow in the argument to the exponential function. These actions do not change the result, but lead to more numerical stability. However, arguments to offset are not scaled since there are situations where a large offset value is a purposefully used. Users should not use normally allow large numeric offset values.

### Value

an object of class `coxph` representing the fit. See `coxph.object` for details.

### Side Effects

Depending on the call, the `predict`, `residuals`, and `survfit` routines may need to reconstruct the x matrix created by `coxph`. It is possible for this to fail, as in the example below in which the `predict` function is unable to find `tform`.

```
tfun <- function(tform) coxph(tform, data=lung)
fit <- tfun(Surv(time, status) ~ age)
predict(fit)
```

In such a case add the `model=TRUE` option to the `coxph` call to obviate the need for reconstruction, at the expense of a larger `fit` object.

## Special terms

There are three special terms that may be used in the model equation. A `strata` term identifies a stratified Cox model; separate baseline hazard functions are fit for each strata. The `cluster` term is used to compute a robust variance for the model. The term `+ cluster(id)` where each value of `id` is unique is equivalent to specifying the `robust=T` argument. If the `id` variable is not unique, it is assumed that it identifies clusters of correlated observations. The robust estimate arises from many different arguments and thus has had many labels. It is variously known as the Huber sandwich estimator, White's estimate (linear models/econometrics), the Horvitz-Thompson estimate (survey sampling), the working independence variance (generalized estimating equations), the infinitesimal jackknife, and the Wei, Lin, Weissfeld (WLW) estimate.

A time-transform term allows variables to vary dynamically in time. In this case the `tt` argument will be a function or a list of functions (if there are more than one `tt()` term in the model) giving the appropriate transform. See the examples below.

## Convergence

In certain data cases the actual MLE estimate of a coefficient is infinity, e.g., a dichotomous variable where one of the groups has no events. When this happens the associated coefficient grows at a steady pace and a race condition will exist in the fitting routine: either the log likelihood converges, the information matrix becomes effectively singular, an argument to `exp` becomes too large for the computer hardware, or the maximum number of interactions is exceeded. (Nearly always the first occurs.) The routine attempts to detect when this has happened, not always successfully. The primary consequence for the user is that the Wald statistic = coefficient/se(coefficient) is not valid in this case and should be ignored; the likelihood ratio and score tests remain valid however.

## Ties

There are three possible choices for handling tied event times. The Breslow approximation is the easiest to program and hence became the first option coded for almost all computer routines. It then ended up as the default option when other options were added in order to "maintain backwards compatibility". The Efron option is more accurate if there are a large number of ties, and it is the default option here. In practice the number of ties is usually small, in which case all the methods are statistically indistinguishable.

Using the "exact partial likelihood" approach the Cox partial likelihood is equivalent to that for matched logistic regression. (The `clogit` function uses the `coxph` code to do the fit.) It is technically appropriate when the time scale is discrete and has only a few unique values, and some packages refer to this as the "discrete" option. There is also an "exact marginal likelihood" due to Prentice which is not implemented here.

The calculation of the exact partial likelihood is numerically intense. Say for instance 15 of 180 subjects at risk had an event on day 7; then the code needs to compute sums over all  $180 \text{ choose } 15 > 10^{43}$  different possible subsets of size 15. There is an efficient recursive algorithm for this task, but even with this the computation can be insufferably long. With (start, stop) data it is much worse since the recursion needs to start anew for each unique start time.

## Penalized regression

`coxph` can now maximise a penalised partial likelihood with arbitrary user-defined penalty. Supplied penalty functions include ridge regression ([ridge](#)), smoothing splines ([pspline](#)), and frailty models ([frailty](#)).

              event=c(1, 1, 1, 1, 1, 1, 1, 0, 0, 0),
              x     =c(1, 0, 0, 1, 0, 1, 1, 1, 0, 0) )

summary( coxph( Surv(start, stop, event) ~ x, test2))

# Fit a stratified model, clustered on patients

bladder1 <- bladder[bladder$enum < 5, ]
coxph(Surv(stop, event) ~ (rx + size + number) * strata(enum) +
      cluster(id), bladder1)

# Fit a time transform model using current age
coxph(Surv(time, status) ~ ph.ecog + tt(age), data=lung,
      tt=function(x,t,...) pspline(x + t/365.25))
```

---

coxph.control

*Ancillary arguments for controlling coxph fits*

---

## Description

This is used to set various numeric parameters controlling a Cox model fit. Typically it would only be used in a call to `coxph`.

**Usage**

```
coxph.control(eps = 1e-09, toler.chol = .Machine$double.eps^0.75,
iter.max = 20, toler.inf = sqrt(eps), outer.max = 10)
```

**Arguments**

<code>eps</code>	Iteration continues until the relative change in the log partial likelihood is less than <code>eps</code> . Must be positive.
<code>toler.chol</code>	Tolerance for detection of singularity during a Cholesky decomposition of the variance matrix, i.e., for detecting a redundant predictor variable.
<code>iter.max</code>	Maximum number of iterations to attempt for convergence.
<code>toler.inf</code>	Tolerance criteria for the warning message about a possible infinite coefficient value.
<code>outer.max</code>	For a penalized coxph model, e.g. with pspline terms, there is an outer loop of iteration to determine the penalty parameters; maximum number of iterations for this outer loop.

**Value**

a list containing the values of each of the above constants

**Author(s)**

Terry Therneau

coxph.detail	<i>Details of a Cox Model Fit</i>
--------------	-----------------------------------

---

**Description**

Returns the individual contributions to the first and second derivative matrix, at each unique event time.

**Usage**

```
coxph.detail(object, riskmat=FALSE)
```

**Arguments**

<code>object</code>	a Cox model object, i.e., the result of <code>coxph</code> .
<code>riskmat</code>	include the at-risk indicator matrix in the output?

**Details**

This function may be useful for those who wish to investigate new methods or extensions to the Cox model. The example below shows one way to calculate the Schoenfeld residuals.

**Value**

a list with components

<code>time</code>	the vector of unique event times
<code>nevent</code>	the number of events at each of these time points.
<code>means</code>	a matrix with one row for each event time and one column for each variable in the Cox model, containing the weighted mean of the variable at that time, over all subjects still at risk at that time. The weights are the risk weights <code>exp(x %*% fit\$coef)</code> .
<code>nrisk</code>	number of subjects at risk.
<code>score</code>	the contribution to the score vector (first derivative of the log partial likelihood) at each time point.
<code>imat</code>	the contribution to the information matrix (second derivative of the log partial likelihood) at each time point.
<code>hazard</code>	the hazard increment. Note that the hazard and variance of the hazard are always for some particular future subject. This routine uses <code>object\$mean</code> as the future subject.
<code>varhaz</code>	the variance of the hazard increment.
<code>x, y</code>	copies of the input data.
<code>strata</code>	only present for a stratified Cox model, this is a table giving the number of time points of component <code>time</code> that were contributed by each of the strata.
<code>riskmat</code>	a matrix with one row for each time and one column for each observation containing a 0/1 value to indicate whether that observation was (1) or was not (0) at risk at the given time point.

**See Also**

[coxph](#), [residuals.coxph](#)

**Examples**

```
fit <- coxph(Surv(futime,fustat) ~ age + rx + ecog.ps, ovarian, x=TRUE)
fitd <- coxph.detail(fit)
# There is one Schoenfeld residual for each unique death. It is a
# vector (covariates for the subject who died) - (weighted mean covariate
# vector at that time). The weighted mean is defined over the subjects
# still at risk, with exp(X beta) as the weight.

events <- fit$y[,2]==1
etime <- fit$y[events,1] #the event times --- may have duplicates
indx <- match(etime, fitd$time)
schoen <- fit$x[events,] - fitd$means[indx,]
```

coxph.object

*Proportional Hazards Regression Object***Description**

This class of objects is returned by the `coxph` class of functions to represent a fitted proportional hazards model. Objects of this class have methods for the functions `print`, `summary`, `residuals`, `predict` and `survfit`.

**Arguments**

<code>coefficients</code>	the vector of coefficients. If the model is over-determined there will be missing values in the vector corresponding to the redundant columns in the model matrix.
<code>var</code>	the variance matrix of the coefficients. Rows and columns corresponding to any missing coefficients are set to zero.
<code>naive.var</code>	this component will be present only if the <code>robust</code> option was true. If so, the <code>var</code> component will contain the robust estimate of variance, and this component will contain the ordinary estimate.
<code>loglik</code>	a vector of length 2 containing the log-likelihood with the initial values and with the final values of the coefficients.
<code>score</code>	value of the efficient score test, at the initial value of the coefficients.
<code>rscore</code>	the robust log-rank statistic, if a robust variance was requested.
<code>wald.test</code>	the Wald test of whether the final coefficients differ from the initial values.
<code>iter</code>	number of iterations used.
<code>linear.predictors</code>	the vector of linear predictors, one per subject. Note that this vector has been centered, see <code>predict.coxph</code> for more details.
<code>residuals</code>	the martingale residuals.
<code>means</code>	vector of column means of the X matrix. Subsequent survival curves are adjusted to this value.
<code>n</code>	the number of observations used in the fit.
<code>nevent</code>	the number of events (usually deaths) used in the fit.
<code>weights</code>	the vector of case weights, if one was used.
<code>method</code>	the computation method used.
<code>na.action</code>	the <code>na.action</code> attribute, if any, that was returned by the <code>na.action</code> routine. The object will also contain the following, for documentation see the <code>lm</code> object: <code>terms</code> , <code>assign</code> , <code>formula</code> , <code>call</code> , and, optionally, <code>x</code> , <code>y</code> , and/or <code>frame</code> .

**Components**

The following components must be included in a legitimate `coxph` object.

**See Also**

---

coxph.wtest	<i>Compute a quadratic form</i>
-------------	---------------------------------

---

### Description

This function is used internally by several survival routines. It computes a simple quadratic form, while properly dealing with missings.

### Usage

```
coxph.wtest(var, b, toler.chol = 1e-09)
```

### Arguments

var	variance matrix
b	vector
toler.chol	tolerance for the internal choelsky decomposition

### Details

Compute  $b' V^{-1} b$ . Equivalent to `sum(b * solve(V,b))`, except for the case of redundant covariates in the original model, which lead to NA values in V and b.

### Value

a real number

### Author(s)

Terry Therneau

---

dsurvreg	<i>Distributions available in survreg.</i>
----------	--

---

### Description

Density, cumulative distribution function, quantile function and random generation for the set of distributions supported by the `survreg` function.

### Usage

```
dsurvreg(x, mean, scale=1, distribution='weibull', parms)
psurvreg(q, mean, scale=1, distribution='weibull', parms)
qsurvreg(p, mean, scale=1, distribution='weibull', parms)
rsurvreg(n, mean, scale=1, distribution='weibull', parms)
```

## Arguments

<code>x</code>	vector of quantiles. Missing values (NAs) are allowed.
<code>q</code>	vector of quantiles. Missing values (NAs) are allowed.
<code>p</code>	vector of probabilities. Missing values (NAs) are allowed.
<code>n</code>	number of random deviates to produce
<code>mean</code>	vector of linear predictors for the model. This is replicated to be the same length as <code>p</code> , <code>q</code> or <code>n</code> .
<code>scale</code>	vector of (positive) scale factors. This is replicated to be the same length as <code>p</code> , <code>q</code> or <code>n</code> .
<code>distribution</code>	character string giving the name of the distribution. This must be one of the elements of <code>survreg.distributions</code>
<code>parms</code>	optional parameters, if any, of the distribution. For the t-distribution this is the degrees of freedom.

## Details

Elements of `q` or `p` that are missing will cause the corresponding elements of the result to be missing. The `location` and `scale` values are as they would be for `survreg`. The label "mean" was an unfortunate choice (made in mimicry of `qnorm`); since almost none of these distributions are symmetric it will not actually be a mean, but corresponds instead to the linear predictor of a fitted model. Translation to the usual parameterization found in a textbook is not always obvious. For example, the Weibull distribution is fit using the Extreme value distribution along with a log transformation. Letting  $F(t) = 1 - \exp[-(at)^p]$  be the cumulative distribution of the Weibull using a standard parameterization in terms of  $a$  and  $p$ , the `survreg` location corresponds to  $-\log(a)$  and the scale to  $1/p$  (Kalbfleish and Prentice, section 2.2.2).

## Value

density (`dsurvreg`), probability (`psurvreg`), quantile (`qsurvreg`), or for the requested distribution with mean and scale parameters `mean` and `sd`.

flchain

---

*Assay of serum free light chain for 7874 subjects.*

---

## Description

This is a stratified random sample containing 1/2 of the subjects from a study of the relationship between serum free light chain (FLC) and mortality. The original sample contains samples on approximately 2/3 of the residents of Olmsted County aged 50 or greater.

## Usage

```
data(flchain)
```

## Format

A data frame with 7874 persons containing the following variables.

age age in years

sex F=female, M=male

sample.yr the calendar year in which a blood sample was obtained

kappa serum free light chain, kappa portion

lambda serum free light chain, lambda portion

flc.grp the FLC group for the subject, as used in the original analysis

creatinine serum creatinine

mgus 1 if the subject had been diagnosed with monoclonal gammopathy (MGUS)

futime days from enrollment until death. Note that there are 3 subjects whose sample was obtained on their death date.

death 0=alive at last contact date, 1=dead

chapter for those who died, a grouping of their primary cause of death by chapter headings of the International Code of Diseases ICD-9

## Details

In 1995 Dr. Robert Kyle embarked on a study to determine the prevalence of monoclonal gammopathy of undetermined significance (MGUS) in Olmsted County, Minnesota, a condition which is normally only found by chance from a test (serum electrophoresis) which is ordered for other causes. Later work suggested that one component of immunoglobulin production, the serum free light chain, might be a possible marker for immune dysregulation. In 2010 Dr. Angela Dispenzieri and colleagues assayed FLC levels on those samples from the original study for which they had

patient permission and from which sufficient material remained for further testing. They found that elevated FLC levels were indeed associated with higher death rates.

Patients were recruited when they came to the clinic for other appointments, with a final random sample of those who had not yet had a visit since the study began. An interesting side question is whether there are differences between early, mid, and late recruits.

This data set contains an age and sex stratified random sample that includes 7874 of the original 15759 subjects. The original subject identifiers and dates have been removed to protect patient identity. Subsampling was done to further protect this information.

## Source

The primary investigator (A Dispenzieri) and statistician (T Therneau) for the study.

```

---

frailty

*Random effects terms*

---

## Description

The frailty function allows one to add a simple random effects term to a Cox or survreg model.

## Usage

```
frailty(x, distribution="gamma", ...)
frailty.gamma(x, sparse = (nclass > 5), theta, df, eps = 1e-05,
             method = c("em","aic", "df", "fixed"), ...)
frailty.gaussian(x, sparse = (nclass > 5), theta, df,
                method = c("reml","aic", "df", "fixed"), ...)
frailty.t(x, sparse = (nclass > 5), theta, df, eps = 1e-05, tdf = 5,
          method = c("aic", "df", "fixed"), ...)
```

## Arguments

<code>x</code>	the variable to be entered as a random effect. It is always treated as a factor.
<code>distribution</code>	either the <code>gamma</code> , <code>gaussian</code> or <code>t</code> distribution may be specified. The routines <code>frailty.gamma</code> , <code>frailty.gaussian</code> and <code>frailty.t</code> do the actual work.
<code>...</code>	Arguments for specific distribution, including (but not limited to)
<code>sparse</code>	cutoff for using a sparse coding of the data matrix. If the total number of levels of <code>x</code> is larger than this value, then a sparse matrix approximation is used. The correct cutoff is still a matter of exploration: if the number of levels is very large (thousands) then the non-sparse calculation may not be feasible in terms of both memory and compute time. Likewise, the accuracy of the sparse approximation appears to be related to the maximum proportion of subjects in any one class, being best when no one class has a large membership.
<code>theta</code>	if specified, this fixes the variance of the random effect. If not, the variance is a parameter, and a best solution is sought. Specifying this implies <code>method='fixed'</code> .
<code>df</code>	if specified, this fixes the degrees of freedom for the random effect. Specifying this implies <code>method='df'</code> . Only one of <code>theta</code> or <code>df</code> should be specified.
<code>method</code>	the method used to select a solution for <code>theta</code> , the variance of the random effect. The <code>fixed</code> corresponds to a user-specified value, and no iteration is done. The <code>df</code> selects the variance such that the degrees of freedom for the random effect matches a user specified value. The <code>aic</code> method seeks to maximize Akaike's information criteria $2*(\text{partial likelihood} - \text{df})$ . The <code>em</code> and <code>reml</code> methods are specific to Cox models with <code>gamma</code> and <code>gaussian</code> random effects, respectively. Please see further discussion below.
<code>tdf</code>	the degrees of freedom for the t-distribution.
<code>eps</code>	convergence criteria for the iteration on <code>theta</code> .

## Details

The `frailty` plugs into the general penalized modeling framework provided by the `coxph` and `survreg` routines. This framework deals with likelihood, penalties, and degrees of freedom; these aspects work well with either parent routine.

Therneau, Grambsch, and Pankratz show how maximum likelihood estimation for the Cox model with a `gamma` frailty can be accomplished using a general penalized routine, and Ripatti and Palmgren work through a similar argument for the Cox model with a `gaussian` frailty. Both of these are specific to the Cox model. Use of `gamma/ml` or `gaussian/reml` with `survreg` does not lead to valid results.

The extensible structure of the penalized methods is such that the penalty function, such as `frailty` or `pspine`, is completely separate from the modeling routine. The strength of this is that a user can plug in any penalization routine they choose. A weakness is that it is very difficult for the modeling routine to know whether a sensible penalty routine has been supplied.

Note that use of a `frailty` term implies a mixed effects model and use of a `cluster` term implies a GEE approach; these cannot be mixed.

The `coxme` package has superseded this method. It is faster, more stable, and more flexible.

## Value

this function is used in the model statement of either `coxph` or `survreg`. It's results are used internally.

---

is.ratetable	Verify that an object is of class ratetable.
--------------	--

---

### Description

The function verifies not only the `class` attribute, but the structure of the object.

### Usage

```
is.ratetable(x, verbose=FALSE)
```

### Arguments

<code>x</code>	the object to be verified.
<code>verbose</code>	if TRUE and the object is not a ratetable, then return a character string describing the way(s) in which <code>x</code> fails to be a proper ratetable object.

### Details

Rate tables are used by the `pyears` and `survexp` functions, and normally contain death rates for some population, categorized by age, sex, or other variables. They have a fairly rigid structure, and the `verbose` option can help in creating a new rate table.

### Value

returns TRUE if `x` is a ratetable, and FALSE or a description if it is not.

**See Also**

[pyears](#), [survexp](#).

**Examples**

```
is.ratetable(survexp.us) # True
is.ratetable(cancer)    # False
```

---

kidney

*Kidney catheter data*

---

**Description**

Data on the recurrence times to infection, at the point of insertion of the catheter, for kidney patients using portable dialysis equipment. Catheters may be removed for reasons other than infection, in which case the observation is censored. Each patient has exactly 2 observations.

This data has often been used to illustrate the use of random effects (frailty) in a survival model. However, one of the males (id 21) is a large outlier, with much longer survival than his peers. If this observation is removed no evidence remains for a random subject effect.

**Format**

patient:	id
time:	time
status:	event status
age:	in years
sex:	1=male, 2=female
disease:	disease type (0=GN, 1=AN, 2=PKD, 3=Other)
frail:	frailty estimate from original paper

**Note**

The original paper ignored the issue of tied times and so is not exactly reproduced by the survival package.

**Source**

CA McGilchrist, CW Aisbett (1991), Regression with frailty in survival analysis. *Biometrics* **47**, 461–66.

**Examples**

```
kfit <- coxph(Surv(time, status)~ age + sex + disease + frailty(id), kidney)
kfit0 <- coxph(Surv(time, status)~ age + sex + disease, kidney)
kfitml <- coxph(Surv(time, status) ~ age + sex + disease +
  frailty(id, dist='gauss'), kidney)
```

---

lines.survfit

Add Lines or Points to a Survival Plot

---

## Description

Often used to add the expected survival curve(s) to a Kaplan-Meier plot generated with `plot.survfit`.

## Usage

```
## S3 method for class 'survfit'
lines(x, type="s", mark=3, col=1, lty=1,
      lwd=1, cex=1, mark.time=TRUE,
      xscale=1, firstx=0, firsty=1, xmax, fun, conf.int=FALSE, ...)
## S3 method for class 'survexp'
lines(x, type="l", ...)
## S3 method for class 'survfit'
points(x, xscale, xmax, fun, ...)
```

## Arguments

<code>x</code>	a survival object, generated from the <code>survfit</code> or <code>survexp</code> functions.
<code>type</code>	the line type, as described in <code>lines</code> . The default is a step function for <code>survfit</code> objects, and a connected line for <code>survexp</code> objects. All other arguments for <code>lines.survexp</code> are identical to those for <code>lines.survfit</code> .
<code>mark, col, lty, lwd, cex</code>	vectors giving the mark symbol, color, line type, line width and character size for the added curves.
<code>...</code>	other graphical parameters
<code>mark.time</code>	controls the labeling of the curves. If <code>FALSE</code> , no labeling is done. If <code>TRUE</code> , then curves are marked at each censoring time. If <code>mark.time</code> is a numeric vector, then curves are marked at the specified time points.
<code>xscale</code>	a number used to divide the <code>x</code> values. If time was originally in days, a value of 365.25 would give a plotted scale in years.
<code>firstx, firsty</code>	the starting point for the survival curves. If either of these is set to <code>NA</code> or <code>&lt; blank</code> the plot will start at the first time point of the curve.
<code>xmax</code>	the maximum horizontal plot coordinate. This shortens the curve before plotting it, so unlike using the <code>xlim</code> graphical parameter, warning messages about out of bounds points are not generated.
<code>fun</code>	an arbitrary function defining a transformation of the survival curve. For example <code>fun=log</code> is an alternative way to draw a log-survival curve (but with the axis labeled with $\log(S)$ values). Four often used transformations can be specified with a character argument instead: "log" is the same as using the <code>log=T</code> option, "event" plots cumulative events ( $f(y) = 1-y$ ), "cumhaz" plots the cumulative hazard function ( $f(y) = -\log(y)$ ) and "cloglog" creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$ along with log scale for the x-axis).
<code>conf.int</code>	if <code>TRUE</code> , confidence bands for the curves are also plotted. If set to "only", then only the CI bands are plotted, and the curve itself is left off. This can be useful for fine control over the colors or line types of a plot.

## Details

When the `survfit` function creates a multi-state survival curve the resulting object has class `'survfitms'`. The only difference in the plots is that that it defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves default to starting at 1 and going down. All other options are identical.

## Value

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not of the confidence limits). This may be useful for labeling.

## Side Effects

one or more curves are added to the current plot.

## See Also

`lines`, `par`, `plot.survfit`, `survfit`, `survexp`.

## Examples

```
fit <- survfit(Surv(time, status==2) ~ sex, pbc, subset=1:312)
plot(fit, mark.time=FALSE, xscale=365.25,
      xlab='Years', ylab='Survival')
lines(fit[1], lwd=2, xscale=365.24) #darken the first curve and add marks

# Add expected survival curves for the two groups,
# based on the US census data
# The data set does not have entry date, use the midpoint of the study
efit <- survexp(~ ratetable(sex=sex, age=age*365.35, year=as.Date('1979/1/1')) +
                 sex, data=pbcc, times=(0:24)*182)
temp <- lines(efit, lty=2, xscale=365.24, lwd=2:1)
text(temp, c("Male", "Female"), adj= -.1) #labels just past the ends
title(main="Primary Biliary Cirrhosis, Observed and Expected")
```

---

logLik.coxph

logLik method for a Cox model

---

**Description**

The logLik function for survival models

**Usage**

```
## S3 method for class 'coxph'
logLik(object, ...)
## S3 method for class 'survreg'
logLik(object, ...)
```

**Arguments**

object	the result of a coxph or survreg fit
...	optional arguments for other instances of the method

**Details**

The logLik function is used by summary functions in R such as AIC. For a Cox model, this method returns the partial likelihood. The number of degrees of freedom (df) used by the fit and the effective number of observations (nobs) are added as attributes. Per Raftery and others, the effective number of observations is the taken to be the number of events in the data set.

For a survreg model the proper value for the effective number of observations is still an open question (at least to this author). For right censored data the approach of logLik.coxph is the possible the most sensible, but for interval censored observations the result is unclear. The code currently does not add a nobs attribute.

**Value**

an object of class `logLik`

mgus

---

*Monoclonal gammopathy data*

---

## Description

Natural history of 241 subjects with monoclonal gammopathy of undetermined significance (MGUS).

## Usage

```
mgus
mgus1
```

## Format

mgus: A data frame with 241 observations on the following 12 variables.

id:	subject id
age:	age in years at the detection of MGUS
sex:	male or female
dxyr:	year of diagnosis
pcdx:	for subjects who progress to a plasma cell malignancy the subtype of malignancy: multiple myeloma (MM) is the most common, followed by amyloidosis (AM), macroglobulinemia (MA), and other lymphoproliferative disorders (LP)
pctime:	days from MGUS until diagnosis of a plasma cell malignancy
futime:	days from diagnosis to last follow-up
death:	1= follow-up is until death
alb:	albumin level at MGUS diagnosis
creat:	creatinine at MGUS diagnosis
hgb:	hemoglobin at MGUS diagnosis
mspike:	size of the monoclonal protien spike at diagnosis

mgus1: The same data set in start,stop format. Contains the id, age, sex, and laboratory variable described above along with

start, stop:	sequential intervals of time for each subject
status:	=1 if the interval ends in an event
event:	a factor containing the event type: censor, death, or plasma cell malignancy
enum:	event number for each subject: 1 or 2

## Details

Plasma cells are responsible for manufacturing immunoglobulins, an important part of the immune defense. At any given time there are estimated to be about  $10^6$  different immunoglobulins in the circulation at any one time. When a patient has a plasma cell malignancy the distribution will become dominated by a single isotype, the product of the malignant clone, visible as a spike on a serum protein electrophoresis. Monoclonal gammopathy of undetermined significance (MGUS) is the presence of such a spike, but in a patient with no evidence of overt malignancy. This data set of 241 sequential subjects at Mayo Clinic was the groundbreaking study defining the natural history of such subjects. Due to the diligence of the principle investigator 0 subjects have been lost to follow-up.

Three subjects had MGUS detected on the day of death. In data set `mgus1` these subjects have the time to MGUS coded as .5 day before the death in order to avoid tied times.

These data sets were updated in Jan 2015 to correct some small errors.

## Source

Mayo Clinic data courtesy of Dr. Robert Kyle.

## References

## Examples

```
# Create the competing risk curves for time to first of death or PCM
sfit <- survfit(Surv(start, stop, event) ~ sex, mgus1, subset=(enum==1))
print(sfit) # the order of printout is the order in which they plot

plot(sfit, xscale=365.25, lty=c(2,1,2,1), col=c(1,1,2,2),
      xlab="Years after MGUS detection", ylab="Proportion")
legend(0, .8, c("Death/male", "Death/female", "PCM/male", "PCM/female"),
      lty=c(1,1,2,2), col=c(2,1,2,1), bty='n')

title("Curves for the first of plasma cell malignancy or death")
# The plot shows that males have a higher death rate than females (no
# surprise) but their rates of conversion to PCM are essentially the same.
```

---

mgus2

*Monoclonal gammopathy data*

---

## Description

Natural history of 1341 sequential patients with monoclonal gammopathy of undetermined significance (MGUS).

## Usage

```
data("mgus2")
```

**Format**

A data frame with 1384 observations on the following 10 variables.

id subject identifier  
 age age at diagnosis, in years  
 sex a factor with levels F M  
 hgb hemoglobin  
 creat creatinine  
 msplike size of the monoclonal serum spike  
 ptime time until progression to a plasma cell malignancy (PCM) or last contact, in months  
 pstat occurrence of PCM: 0=no, 1=yes  
 futime time until death or last contact, in months  
 death occurrence of death: 0=no, 1=yes

**Details**

This is a larger follow-on study of the condition also found in data set `mgus`.

**Source**

Mayo Clinic data courtesy of Dr. Robert Kyle. All patient identifiers have been removed, age rounded to the nearest year, and follow-up times rounded to the nearest month.

**References**

---

`model.frame.coxph` *Model.frame method for coxph objects*

---

**Description**

Recreate the model frame of a `coxph` fit.

**Usage**

```
## S3 method for class 'coxph'
model.frame(formula, ...)
```

**Arguments**

`formula` the result of a `coxph` fit  
`...` other arguments to `model.frame`

**Details**

For details, see the manual page for the generic function. This function would rarely be called by a user, it is mostly used inside functions like `residual` that need to recreate the data set from a model in order to do further calculations.

**Value**

the model frame used in the original fit, or a parallel one for new data.

**Author(s)**

Terry Therneau

**See Also**

[model.frame](#)

---

`model.matrix.coxph` *Model.matrix method for coxph models*

---

**Description**

Reconstruct the model matrix for a cox model.

**Usage**

```
## S3 method for class 'coxph'
model.matrix(object, data=NULL, contrast.arg =
  object$contrasts, ...)
```

**Arguments**

<code>object</code>	the result of a <code>coxph</code> model
<code>data</code>	optional, a data frame from which to obtain the data
<code>contrast.arg</code>	optional, a contrasts object describing how factors should be coded
<code>...</code>	other possible argument to <code>model.frame</code>

**Details**

When there is a `data` argument this function differs from most of the other `model.matrix` methods in that the response variable for the original formula is *not* required to be in the data.

If the data frame contains a `terms` attribute then it is assumed to be the result of a call to `model.frame`, otherwise a call to `model.frame` is applied with the data as an argument.

**Value**

The model matrix for the fit

**Author(s)**

Terry Therneau

**See Also**`model.matrix`**Examples**

```
fit1 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung)
xfit <- model.matrix(fit1)

fit2 <- coxph(Surv(time, status) ~ age + factor(ph.ecog), data=lung,
              x=TRUE)
all.equal(model.matrix(fit1), fit2$x)
```

---

neardate	<i>Find the index of the closest value in data set 2, for each entry in data set one.</i>
----------	---

---

**Description**

A common task in medical work is to find the closest lab value to some index date, for each subject.

**Usage**

```
neardate(id1, id2, y1, y2, best = c("after", "prior"),
nomatch = NA_integer_)
```

**Arguments**

<code>id1</code>	vector of subject identifiers for the index group
<code>id2</code>	vector of identifiers for the reference group
<code>y1</code>	normally a vector of dates for the index group, but any orderable data type is allowed
<code>y2</code>	reference set of dates
<code>best</code>	find the index of the first <code>y2</code> value prior to or equal to the target <code>y1</code> value, for each subject, or the one after?
<code>nomatch</code>	the value to return for items without a match

**Details**

This routine is closely related to `match` and to `findInterval`, the first of which finds exact matches and the second closest matches. This finds the closest matching date within sets of exactly matching identifiers. Closest date matching is often needed in clinical studies. For example data set 1 might contain the subject identifier and the date of some procedure and data set set 2 has the dates and values for laboratory tests, and the query is to find the first test value after the intervention but no closer than 7 days.

The `id1` and `id2` arguments are similar to `match` in that we are searching for instances of `id1` that will be found in `id2`, and the result is the same length as `id1`. However, instead of returning the first match with `id2` this routine returns the one that best matches with respect to `y1`.

The `y1` and `y2` arguments need not be dates, the function works for any data type such that the expression `c(y1, y2)` gives a sensible, sortable result. Be careful about matching Date and

DateTime values and the impact of time zones, however, see [as.POSIXct](#). If `y1` and `y2` are not of the same class the user is on their own. Since there exist pairs of unmatched data types where the result could be sensible, the routine will in this case proceed under the assumption that "the user knows what they are doing". Caveat emptor.

### Value

the index of the matching observations in the second data set, or the `nomatch` value for no successful match

### Author(s)

Terry Therneau

### See Also

[match](#), [findInterval](#)

### Examples

```
data1 <- data.frame(id = 1:10,
                    entry.dt = as.Date(paste("2011", 1:10, "5", sep='-')))
templ <- c(1,4,5,1,3,6,9, 2,7,8,12,4,6,7,10,12,3)
data2 <- data.frame(id = c(1,1,1,2,2,4,4,5,5,5,6,8,8,9,10,10,12),
                    lab.dt = as.Date(paste("2011", templ, "1", sep='-')),
                    chol = round(runif(17, 130, 280)))

#first cholesterol on or after enrollment
indx1 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt)
data2[indx1, "chol"]

# Closest one, either before or after.
#
indx2 <- neardate(data1$id, data2$id, data1$entry.dt, data2$lab.dt,
                 best="prior")
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
              ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
                     abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1)))

# closest date before or after, but no more than 21 days prior to index
indx2 <- ifelse((data1$entry.dt - data2$lab.dt[indx2]) >21, NA, indx2)
ifelse(is.na(indx1), indx2, # none after, take before
       ifelse(is.na(indx2), indx1, #none before
              ifelse(abs(data2$lab.dt[indx2]- data1$entry.dt) <
                     abs(data2$lab.dt[indx1]- data1$entry.dt), indx2, indx1)))
```

### Description

Missing data/masurement error example. Tumor histology predicts survival, but prediction is stronger with central lab histology than with the local institution determination.

**Usage**

```
nwtco
```

**Format**

A data frame with 4028 observations on the following 9 variables.

```
seqno id number
instit Histology from local institution
histol Histology from central lab
stage Disease stage
study study
rel indicator for relapse
edrel time to relapse
age age in months
in.subcohort Included in the subcohort for the example in the paper
```

---

pbc

*Mayo Clinic Primary Biliary Cirrhosis Data*

---

**Description**

D This data is from the Mayo Clinic trial in primary biliary cirrhosis (PBC) of the liver conducted between 1974 and 1984. A total of 424 PBC patients, referred to Mayo Clinic during that ten-year interval, met eligibility criteria for the randomized placebo controlled trial of the drug D-penicillamine. The first 312 cases in the data set participated in the randomized trial and contain largely complete data. The additional 112 cases did not participate in the clinical trial, but consented to have basic measurements recorded and to be followed for survival. Six of those cases were lost to follow-up shortly after diagnosis, so the data here are on an additional 106 cases as well as the 312 randomized participants.

A nearly identical data set found in appendix D of Fleming and Harrington; this version has fewer missing values.

## Description

This data is a continuation of the PBC data set, and contains the follow-up laboratory data for each study patient. An analysis based on the data can be found in Murtagh, et. al.

The primary PBC data set contains only baseline measurements of the laboratory paramters. This data set contains multiple laboratory results, but only on the 312 randomized patients. Some baseline data values in this file differ from the original PBC file, for instance, the data errors in prothrombin time and age which were discovered after the original analysis (see Fleming and Harrington, figure 4.6.7).

One "feature" of the data deserves special comment. The last observation before death or liver transplant often has many more missing covariates than other data rows. The original clinical protocol for these patients specified visits at 6 months, 1 year, and annually thereafter. At these protocol visits lab values were obtained for a large pre-specified battery of tests. "Extra" visits, often undertaken because of worsening medical condition, did not necessarily have all this lab work. The missing values are thus potentially informative.

plot.aareg

*Plot an aareg object.*

---

### Description

Plot the estimated coefficient function(s) from a fit of Aalen's additive regression model.

**Usage**

```
## S3 method for class 'aareg'
plot(x, se=TRUE, maxtime, type='s', ...)
```

**Arguments**

x	the result of a call to the <code>aareg</code> function
se	if TRUE, standard error bands are included on the plot
maxtime	upper limit for the x-axis.
type	graphical parameter for the type of line, default is "steps".
...	other graphical parameters such as line type, color, or axis labels.

**Side Effects**

A plot is produced on the current graphical device.

**References**

**See Also**

`aareg`

---

`plot.cox.zph`

*Graphical Test of Proportional Hazards*

---

**Description**

Displays a graph of the scaled Schoenfeld residuals, along with a smooth curve.

**Usage**

```
## S3 method for class 'cox.zph'
plot(x, resid=TRUE, se=TRUE, df=4, nsmo=40, var, ...)
```

**Arguments**

x	result of the <code>cox.zph</code> function.
resid	a logical value, if TRUE the residuals are included on the plot, as well as the smooth fit.
se	a logical value, if TRUE, confidence bands at two standard errors will be added.
df	the degrees of freedom for the fitted natural spline, <code>df=2</code> leads to a linear fit.
nsmo	number of points used to plot the fitted spline.
var	the set of variables for which plots are desired. By default, plots are produced in turn for each variable of a model. Selection of a single variable allows other features to be added to the plot, e.g., a horizontal line at zero or a main title. This has been superseded by a subscripting method; see the example below.
...	additional graphical arguments passed to the <code>plot</code> function.

## Side Effects

a plot is produced on the current graphics device.

## See Also

## Examples

```
vfit <- coxph(Surv(time,status) ~ trt + factor(celltype) +
              karno + age, data=veteran, x=TRUE)
temp <- cox.zph(vfit)
plot(temp, var=5)      # Look at Karnofsky score, old way of doing plot
plot(temp[5])          # New way with subscripting
abline(0, 0, lty=3)
# Add the linear fit as well
abline(lm(temp$y[,5] ~ temp$x)$coefficients, lty=4, col=3)
title(main="VA Lung Study")
```

---

plot.survfit

*Plot method for survfit objects*

---

## Description

A plot of survival curves is produced, one curve for each strata. The `log=T` option does extra work to avoid `log(0)`, and to try to create a pleasing result. If there are zeros, they are plotted by default at 0.8 times the smallest non-zero value on the curve(s).

Curves are plotted in the same order as they are listed by `print` (which gives a 1 line summary of each). This will be the order in which `col`, `lty`, etc are used.

## Usage

```
## S3 method for class 'survfit'
plot(x, conf.int=, mark.time=TRUE,
     mark=3, col=1, lty=1, lwd=1, cex=1, log=FALSE, xscale=1, yscale=1,
     firstx=0, firsty=1, xmax, ymin=0, fun,
     xlab="", ylab="", xaxs="S", ...)
```

## Arguments

<code>x</code>	an object of class <code>survfit</code> , usually returned by the <code>survfit</code> function.
<code>conf.int</code>	determines whether confidence intervals will be plotted. The default is to do so if there is only 1 curve, i.e., no strata.
<code>mark.time</code>	controls the labeling of the curves. If set to <code>FALSE</code> , no labeling is done. If <code>TRUE</code> , then curves are marked at each censoring time which is not also a death time. If <code>mark.time</code> is a numeric vector, then curves are marked at the specified time points.
<code>mark</code>	vector of mark parameters, which will be used to label the curves. The <code>lines</code> help file contains examples of the possible marks. The vector is reused cyclically if it is shorter than the number of curves.

<code>col</code>	a vector of integers specifying colors for each curve. The default value is 1.
<code>lty</code>	a vector of integers specifying line types for each curve. The default value is 1.
<code>lwd</code>	a vector of numeric values for line widths. The default value is 1.
<code>cex</code>	a numeric value specifying the size of the marks. This is not treated as a vector; all marks have the same size.
<code>log</code>	a logical value, if TRUE the y axis will be on a log scale. Alternately, one of the standard character strings "x", "y", or "xy" can be given to specific logarithmic horizontal and/or vertical axes.
<code>yscale</code>	a numeric value used to multiply the labels on the y axis. A value of 100, for instance, would be used to give a percent scale. Only the labels are changed, not the actual plot coordinates, so that adding a curve with <code>"lines(surv.exp(...))"</code> , say, will perform as it did without the <code>yscale</code> argument.
<code>xscale</code>	a numeric value used like <code>yscale</code> for labels on the x axis. A value of 365.25 will give labels in years instead of the original days.
<code>firstx, firsty</code>	the starting point for the survival curves. If either of these is set to NA the plot will start at the first time point of the curve. By default, the plot program obeys tradition by having the plot start at (0,0). If <code>start.time</code> argument is used in <code>survfit</code> , <code>firstx</code> is set to that value.
<code>xmax</code>	the maximum horizontal plot coordinate. This can be used to shrink the range of a plot. It shortens the curve before plotting it, so that unlike using the <code>xlim</code> graphical parameter, warning messages about out of bounds points are not generated.
<code>ymin</code>	lower boundary for y values. Survival curves are most often drawn in the range of 0-1, even if none of the curves approach zero. The parameter is ignored if the <code>fun</code> argument is present, or if it has been set to NA.
<code>fun</code>	an arbitrary function defining a transformation of the survival curve. For example <code>fun=log</code> is an alternative way to draw a log-survival curve (but with the axis labeled with $\log(S)$ values), and <code>fun=sqrt</code> would generate a curve on square root scale. Four often used transformations can be specified with a character argument instead: <code>"log"</code> is the same as using the <code>log=T</code> option, <code>"event"</code> plots cumulative events ( $f(y) = 1-y$ ), <code>"cumhaz"</code> plots the cumulative hazard function ( $f(y) = -\log(y)$ ), and <code>"cloglog"</code> creates a complimentary log-log survival plot ( $f(y) = \log(-\log(y))$ ) along with log scale for the x-axis).
<code>xlab</code>	label given to the x-axis.
<code>ylab</code>	label given to the y-axis.
<code>xaxis</code>	either "S" for a survival curve or a standard x axis style as listed in <code>par</code> . Survival curves are usually displayed with the curve touching the y-axis, but not touching the bounding box of the plot on the other 3 sides. Type "S" accomplishes this by manipulating the plot range and then using the "i" style internally.
<code>...</code>	for future methods

## Details

When the `survfit` function creates a multi-state survival curve the resulting object also has class `'survfitms'`. Competing risk curves are a common case. The only difference in the plots is that multi-state defaults to a curve that goes from lower left to upper right (starting at 0), where survival curves by default start at 1 and go down. All other options are identical.

**Value**

a list with components `x` and `y`, containing the coordinates of the last point on each of the curves (but not the confidence limits). This may be useful for labeling.

plot(leukemia.surv, lty = 2:3)
legend(100, .9, c("Maintenance", "No Maintenance"), lty = 2:3)
title("Kaplan-Meier Curves\nfor AML Maintenance Study")
lsurv2 <- survfit(Surv(time, status) ~ x, aml, type='fleming')
plot(lsurv2, lty=2:3, fun="cumhaz",
     xlab="Months", ylab="Cumulative Hazard")
```

---

predict.coxph

*Predictions for a Cox model*

---

**Description**

Compute fitted values and regression terms for a model fitted by [coxph](#)

**Usage**

```
## S3 method for class 'coxph'
predict(object, newdata,
        type=c("lp", "risk", "expected", "terms"),
        se.fit=FALSE, na.action=na.pass, terms=names(object$assign), collapse,
        reference=c("strata", "sample"), ...)
```

**Arguments**

<code>object</code>	the results of a <code>coxph</code> fit.
<code>newdata</code>	Optional new data at which to do predictions. If absent predictions are for the data frame used in the original fit. When <code>coxph</code> has been called with a formula argument created in another context, i.e., <code>coxph</code> has been called within another function and the formula was passed as an argument to that function, there can be problems finding the data set. See the note below.
<code>type</code>	the type of predicted value. Choices are the linear predictor ( <code>"lp"</code> ), the risk score $\exp(lp)$ ( <code>"risk"</code> ), the expected number of events given the covariates and follow-up time ( <code>"expected"</code> ), and the terms of the linear predictor ( <code>"terms"</code> ).
<code>se.fit</code>	if TRUE, pointwise standard errors are produced for the predictions.
<code>na.action</code>	applies only when the <code>newdata</code> argument is present, and defines the missing value action for the new data. The default is to include all observations. When there is no <code>newdata</code> , then the behavior of missing is dictated by the <code>na.action</code> option of the original fit.

terms	if type="terms", this argument can be used to specify which terms should be included; the default is all.
collapse	optional vector of subject identifiers. If specified, the output will contain one entry per subject rather than one entry per observation.
reference	reference for centering predictions, see details below
...	For future methods

### Details

The Cox model is a *relative* risk model; predictions of type "linear predictor", "risk", and "terms" are all relative to the sample from which they came. By default, the reference value for each of these is the mean covariate within strata. The primary underlying reason is statistical: a Cox model only predicts relative risks between pairs of subjects within the same strata, and hence the addition of a constant to any covariate, either overall or only within a particular stratum, has no effect on the fitted results. Using the `reference="strata"` option causes this to be true for predictions as well.

When the results of `predict` are used in further calculations it may be desirable to use a fixed reference level. Use of `reference="sample"` will use the overall means, and agrees with the `linear.predictors` component of the `coxph` object (which uses the overall mean for backwards compatibility with older code). Predictions of type="terms" are almost invariably passed forward to further calculation, so for these we default to using the sample as the reference.

Predictions of type "expected" incorporate the baseline hazard and are thus absolute instead of relative; the `reference` option has no effect on these.

Models that contain a `frailty` term are a special case: due to the technical difficulty, when there is a `newdata` argument the predictions will always be for a random effect of zero.

### Value

a vector or matrix of predictions, or a list containing the predictions (element "fit") and their standard errors (element "se.fit") if the `se.fit` option is TRUE.

### Note

Some predictions can be obtained directly from the `coxph` object, and for others it is necessary for the routine to have the entirety of the original data set, e.g., for type = `terms` or if standard errors are requested. This extra information is saved in the `coxph` object if `model=TRUE`, if not the original data is reconstructed. If it is known that such residuals will be required overall execution will be slightly faster if the model information is saved.

In some cases the reconstruction can fail. The most common is when `coxph` has been called inside another function and the formula was passed as one of the arguments to that enclosing function. Another is when the data set has changed between the original call and the time of the prediction call. In each of these the simple solution is to add `model=TRUE` to the original `coxph` call.

### See Also

### Examples

```
options(na.action=na.exclude) # retain NA in predictions
fit <- coxph(Surv(time, status) ~ age + ph.ecog + strata(inst), lung)
#lung data set has status coded as 1/2
```

```

mresid <- (lung$status-1) - predict(fit, type='expected') #Martingale resid
predict(fit,type="lp")
predict(fit,type="expected")
predict(fit,type="risk",se.fit=TRUE)
predict(fit,type="terms",se.fit=TRUE)

```

---

predict.survreg	<i>Predicted Values for a 'survreg' Object</i>
-----------------	--

---

## Description

Predicted values for a survreg object

## Usage

```

## S3 method for class 'survreg'
predict(object, newdata,
  type=c("response", "link", "lp", "linear", "terms", "quantile",
    "uquantile"),
  se.fit=FALSE, terms=NULL, p=c(0.1, 0.9), na.action=na.pass, ...)

```

## Arguments

object	result of a model fit using the survreg function.
newdata	data for prediction. If absent predictions are for the subjects used in the original fit.
type	the type of predicted value. This can be on the original scale of the data (response), the linear predictor ("linear", with "lp" as an allowed abbreviation), a predicted quantile on the original scale of the data ("quantile"), a quantile on the linear predictor scale ("uquantile"), or the matrix of terms for the linear predictor ("terms"). At this time "link" and linear predictor ("lp") are identical.
se.fit	if TRUE, include the standard errors of the prediction in the result.
terms	subset of terms. The default for residual type "terms" is a matrix with one column for every term (excluding the intercept) in the model.
p	vector of percentiles. This is used only for quantile predictions.
na.action	applies only when the newdata argument is present, and defines the missing value action for the new data. The default is to include all observations.
...	for future methods

## Value

a vector or matrix of predicted values.

```

---

<code>print.aareg</code>	<i>Print an aareg object</i>
--------------------------	------------------------------

---

Description

Print out a fit of Aalen’s additive regression model

Usage

```
## S3 method for class 'aareg'
print(x, maxtime, test=c("aalen", "nrisk"), scale=1,...)
```

Arguments

<code>x</code>	the result of a call to the <code>aareg</code> function
<code>maxtime</code>	the upper time point to be used in the test for non-zero slope
<code>test</code>	the weighting to be used in the test for non-zero slope. The default weights are based on the variance of each coefficient, as a function of time. The alternative weight is proportional to the number of subjects still at risk at each time point.
<code>scale</code>	scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10-4); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.
<code>...</code>	for future methods

**Details**

The estimated increments in the coefficient estimates can become quite unstable near the end of follow-up, due to the small number of observations still at risk in a data set. Thus, the test for slope will sometimes be more powerful if this last 'tail' is excluded.

**Value**

the calling argument is returned.

**Side Effects**

the results of the fit are displayed.

`print.survfit`

---

*Print a Short Summary of a Survival Curve*

---

**Description**

Print number of observations, number of events, the restricted mean survival and its standard error, and the median survival with confidence limits for the median.

**Usage**

```
## S3 method for class 'survfit'
print(x, scale=1, digits = max(options()$digits - 4, 3),
      print.rmean=getOption("survfit.print.rmean"),
      rmean = getOption('survfit.rmean'), ...)
```

**Arguments**

<code>x</code>	the result of a call to the <code>survfit</code> function.
<code>scale</code>	a numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale=365</code> would scale the printout to years.
<code>digits</code>	Number of digits to print
<code>print.rmean, rmean</code>	Options for computation and display of the restricted mean.
<code>...</code>	for future results

**Details**

The mean and its variance are based on a truncated estimator. That is, if the last observation(s) is not a death, then the survival curve estimate does not go to zero and the mean is undefined. There are four possible approaches to resolve this, which are selected by the `rmean` option. The first is to set the upper limit to a constant, e.g., `rmean=365`. In this case the reported mean would be the expected number of days, out of the first 365, that would be experienced by each group. This is useful if interest focuses on a fixed period. Other options are `"none"` (no estimate), `"common"` and `"individual"`. The `"common"` option uses the maximum time for all curves in the object as a common upper limit for the auc calculation. For the `"individual"` options the mean is computed as the area under each curve, over the range from 0 to the maximum observed time for that curve. Since the end point is random, values for different curves are not comparable and the printed standard errors are an underestimate as they do not take into account this random variation. This option is provided mainly for backwards compatability, as this estimate was the default (only)

one in earlier releases of the code. Note that SAS (as of version 9.3) uses the integral up to the last *event* time of each individual curve; we consider this the worst of the choices and do not provide an option for that calculation.

The median and its confidence interval are defined by drawing a horizontal line at 0.5 on the plot of the survival curve and its confidence bands. The intersection of the line with the lower CI band defines the lower limit for the median's interval, and similarly for the upper band. If any of the intersections is not a point, then we use the smallest point of intersection, e.g., if the survival curve were exactly equal to 0.5 over an interval.

### Value

`x`, with the invisible flag set to prevent printing. (The default for all print functions in R is to return the object passed to them; `print.survfit` complies with this pattern. If you want to capture these printed results for further processing, see the `table` component of `summary.survfit`.)

### Side Effects

The number of observations, the number of events, the median survival with its confidence interval, and optionally the restricted mean survival (`rmean`) and its standard error, are printed. If there are multiple curves, there is one line of output for each.

---

pspline	<i>Smoothing splines using a pspline basis</i>
---------	--

---

### Description

Specifies a penalised spline basis for the predictor. This is done by fitting a comparatively small set of splines and penalising the integrated second derivative. Traditional smoothing splines use one basis per observation, but several authors have pointed out that the final results of the fit are indistinguishable for any number of basis functions greater than about 2-3 times the degrees of freedom. Eilers and Marx point out that if the basis functions are evenly spaced, this leads to significant computational simplifications.

### Usage

```
pspline(x, df=4, theta, nterm=2.5 * df, degree=3, eps=0.1, method,
        Boundary.knots=range(x), intercept=FALSE, penalty=TRUE, ...)
```

```
psplineinverse(x)
```

**Arguments**

<code>x</code>	for <code>pspline</code> : a covariate vector. The function does not apply to factor variables. For <code>psplineinverse</code> <code>x</code> will be the result of a <code>pspline</code> call.
<code>df</code>	the desired degrees of freedom. One of the arguments <code>df</code> or <code>theta</code> must be given, but not both. If <code>df=0</code> , then the AIC = (loglik -df) is used to choose an "optimal" degrees of freedom. If AIC is chosen, then an optional argument <code>'caic=T'</code> can be used to specify the corrected AIC of Hurvich et. al.
<code>theta</code>	roughness penalty for the fit. It is a monotone function of the degrees of freedom, with <code>theta=1</code> corresponding to a linear fit and <code>theta=0</code> to an unconstrained fit of <code>nterm</code> degrees of freedom.
<code>nterm</code>	number of splines in the basis
<code>degree</code>	degree of splines
<code>eps</code>	accuracy for <code>df</code>
<code>method</code>	the method for choosing the tuning parameter <code>theta</code> . If <code>theta</code> is given, then <code>'fixed'</code> is assumed. If the degrees of freedom is given, then <code>'df'</code> is assumed. If <code>method='aic'</code> then the degrees of freedom is chosen automatically using Akaike's information criterion.
<code>...</code>	optional arguments to the control function
<code>Boundary.knots</code>	the spline is linear beyond the boundary knots. These default to the range of the data.
<code>intercept</code>	if TRUE, the basis functions include the intercept.
<code>penalty</code>	if FALSE a large number of attributes having to do with penalized fits are excluded. Most useful for exploring the code so as to return a matrix with few added attributes.

**Value**

Object of class `pspline`, `coxph.penalty` containing the spline basis, with the appropriate attributes to be recognized as a penalized term by the `coxph` or `survreg` functions.

For `psplineinverse` the original `x` vector is reconstructed.

pyears

*Person Years*

## Description

This function computes the person-years of follow-up time contributed by a cohort of subjects, stratified into subgroups. It also computes the number of subjects who contribute to each cell of the output table, and optionally the number of events and/or expected number of events in each cell.

## Usage

```

pyears(formula, data, weights, subset, na.action, rmap,
       ratetable, scale=365.25, expect=c('event', 'pyears'),
       model=FALSE, x=FALSE, y=FALSE, data.frame=FALSE)

```

## Arguments

<code>formula</code>	a formula object. The response variable will be a vector of follow-up times for each subject, or a <code>Surv</code> object containing the survival time and an event indicator. The predictors consist of optional grouping variables separated by <code>+</code> operators (exactly as in <code>survfit</code> ), time-dependent grouping variables such as <code>age</code> (specified with <code>tcut</code> ), and optionally a <code>ratetable</code> term. This latter matches each subject to his/her expected cohort.
<code>data</code>	a data frame in which to interpret the variables named in the <code>formula</code> , or in the <code>subset</code> and the <code>weights</code> argument.
<code>weights</code>	case weights.
<code>subset</code>	expression saying that only a subset of the rows of the data should be used in the fit.
<code>na.action</code>	a missing-data filter function, applied to the <code>model.frame</code> , after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
<code>rmap</code>	an optional list that maps data set names to the <code>ratetable</code> names. See the details section below.
<code>ratetable</code>	a table of event rates, such as <code>survexp.uswhite</code> .
<code>scale</code>	a scaling for the results. As most rate tables are in units/day, the default value of 365.25 causes the output to be reported in years.
<code>expect</code>	should the output table include the expected number of events, or the expected number of person-years of observation. This is only valid with a rate table.
<code>data.frame</code>	return a data frame rather than a set of arrays.
<code>model, x, y</code>	If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result.

## Details

Because `pyears` may have several time variables, it is necessary that all of them be in the same units. For instance, in the call

```
py <- pyears(futime ~ rx, rmap=list(age=age, sex=sex, year=entry.dt),
             ratetable=survexp.us)
```

the natural unit of the `ratetable` is hazard per day, it is important that `futime`, `age` and `entry.dt` all be in days. Given the wide range of possible inputs, it is difficult for the routine to do sanity checks of this aspect.

The `ratetable` being used may have different variable names than the user's data set, this is dealt with by the `rmap` argument. The rate table for the above calculation was `survexp.us`, a call to `summary{survexp.us}` reveals that it expects to have variables `age` = age in days, `sex`, and `year` = the date of study entry, we create them in the `rmap` line. The `sex` variable is not mapped, therefore the code assumes that it exists in `mydata` in the correct format. (Note: for factors such as `sex`, the program will match on any unique abbreviation, ignoring case.)

A special function `tcut` is needed to specify time-dependent cutpoints. For instance, assume that `age` is in years, and that the desired final arrays have as one of their margins the age groups 0-2, 2-10, 10-25, and 25+. A subject who enters the study at age 4 and remains under observation for 10 years will contribute follow-up time to both the 2-10 and 10-25 subsets. If `cut(age, c(0, 2, 10, 25, 100))` were used in the formula, the subject would be classified according to his starting age only. The `tcut` function has the same arguments as `cut`, but produces a different output object which allows the `pyears` function to correctly track the subject.

The results of `pyears` are normally used as input to further calculations. The `print` routine, therefore, is designed to give only a summary of the table.

## Value

a list with components:

<code>pyears</code>	an array containing the person-years of exposure. (Or other units, depending on the rate table and the scale). The dimension and dimnames of the array correspond to the variables on the right hand side of the model equation.
<code>n</code>	an array containing the number of subjects who contribute time to each cell of the <code>pyears</code> array.
<code>event</code>	an array containing the observed number of events. This will be present only if the response variable is a <code>Surv</code> object.
<code>expected</code>	an array containing the expected number of events (or person years if <code>expect = "pyears"</code> ). This will be present only if there was a <code>ratetable</code> term.
<code>data</code>	if the <code>data.frame</code> option was set, a data frame containing the variables <code>n</code> , <code>event</code> , <code>pyears</code> and <code>event</code> that supplants the four arrays listed above, along with variables corresponding to each dimension. There will be one row for each cell in the arrays.
<code>offtable</code>	the number of person-years of exposure in the cohort that was not part of any cell in the <code>pyears</code> array. This is often useful as an error check; if there is a mismatch of units between two variables, nearly all the person years may be off table.
<code>summary</code>	a summary of the rate-table matching. This is also useful as an error check.

`call` an image of the call to the function.

`observations` the number of observations in the input data set, after any missings were removed.

`na.action` the `na.action` attribute contributed by an `na.action` routine, if any.

---

quantile.survfit      *Quantiles from a survfit object*

---

### Description

Retrieve quantiles and confidence intervals for them from a `survfit` object.

**Usage**

```
## S3 method for class 'survfit'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
        tolerance= sqrt(.Machine$double.eps), ...)
## S3 method for class 'survfitms'
quantile(x, probs = c(0.25, 0.5, 0.75), conf.int = TRUE,
        tolerance= sqrt(.Machine$double.eps), ...)
```

**Arguments**

<code>x</code>	a result of the <code>survfit</code> function
<code>probs</code>	numeric vector of probabilities with values in [0,1]
<code>conf.int</code>	should lower and upper confidence limits be returned?
<code>tolerance</code>	tolerance for checking that the survival curve exactly equals one of the quantiles
<code>...</code>	optional arguments for other methods

**Details**

The  $k$ th quantile for a survival curve  $S(t)$  is the location at which a horizontal line at height  $p = 1 - k$  intersects the plot of  $S(t)$ . Since  $S(t)$  is a step function, it is possible for the curve to have a horizontal segment at exactly  $1 - k$ , in which case the midpoint of the horizontal segment is returned. This mirrors the standard behavior of the median when data is uncensored. If the survival curve does not fall to  $1 - k$ , then that quantile is undefined.

In order to be consistent with other quantile functions, the argument `prob` of this function applies to the cumulative distribution function  $F(t) = 1 - S(t)$ .

Confidence limits for the values are based on the intersection of the horizontal line at  $1 - k$  with the upper and lower limits for the survival curve. Hence confidence limits use the same  $p$ -value as was in effect when the curve was created, and will differ depending on the `conf.type` option of `survfit`. If the survival curves have no confidence bands, confidence limits for the quantiles are not available.

When a horizontal segment of the survival curve exactly matches one of the requested quantiles the returned value will be the midpoint of the horizontal segment; this agrees with the usual definition of a median for uncensored data. Since the survival curve is computed as a series of products, however, there may be round off error. Assume for instance a sample of size 20 with no tied times and no censoring. The survival curve after the 10th death is  $(19/20)(18/19)(17/18) \dots (10/11) = 10/20$ , but the computed result will not be exactly 0.5. Any horizontal segment whose absolute difference with a requested percentile is less than `tolerance` is considered to be an exact match.

**Value**

The quantiles will be a vector if the `survfit` object contains only a single curve, otherwise it will be a matrix or array. In this case the last dimension will index the quantiles.

If confidence limits are requested, then result will be a list with components `quantile`, `lower`, and `upper`, otherwise it is the vector or matrix of quantiles.

lines(efit, col=2, xscale=365.25) # Add the expected survival line

## End(Not run)
```

---

ratetableDate	<i>Convert date objects to ratetable form</i>
---------------	---

---

### Description

This method converts dates from various forms into the internal form used in `ratetable` objects.

### Usage

```
ratetableDate(x)
```

### Arguments

<code>x</code>	a date. The function currently has methods for <code>Date</code> , <code>date</code> , <code>POSIXt</code> , <code>timeDate</code> , and <code>chron</code> objects.
----------------	--

### Details

This function is useful for those who create new `ratetables`, but is normally invisible to users. It is used internally by the `survexp` and `pyears` functions to map the various date formats; if a new method is added then those routines will automatically be adapted to the new date type.

### Value

a numeric vector, the number of days since 1/1/1960.

### Author(s)

Terry Therneau

### See Also

[pyears](#), [survexp](#)

---

ratetables	<i>Census Data Sets for the Expected Survival and Person Years Functions</i>
------------	--

---

### Description

Census data sets for the expected survival and person years functions.

## Details

**us** total United States population, by age and sex, 1960 to 1980.

**uswhite** United States white population, by age and sex, 1950 to 1980. This is no longer included, but can be extracted from `survexp.usr` as shown in the examples.

**usr** United States population, by age, sex and race, 1960 to 1980. Race is white, nonwhite, or black. For 1960 and 1970 the black population values were not reported separately, so the nonwhite values were used.

**mn** total Minnesota population, by age and sex, 1970 and 1980.

**mnwhite** Minnesota white population, by age and sex, 1960 to 1980.

**fl** total Florida population, by age and sex, 1970 and 1980.

**flr** Florida population, by age, sex and race, 1970-1980. Race is white, nonwhite, or black. For 1970 the black population values were not reported separately, so the nonwhite values were used.

**az** total Arizona population, by age and sex, 1970 and 1980.

**azr** Arizona population, by age, sex and race, 1970-1980. Race is white versus nonwhite. For 1970 the nonwhite population values were not reported separately. In order to make the rate table be a matrix, the 1980 values were repeated. (White and non-white values are quite different).

Each of these tables contains the daily hazard rate for a matched subject from the population, defined as  $-\log(1 - q)/365.24$  where  $q$  is the 1 year probability of death as reported in the original tables. For age 25 in 1970, for instance,  $p = 1 - q$  is the probability that a subject who becomes 25 years of age in 1970 will achieve his/her 26th birthday. The tables are recast in terms of hazard per day entirely for computational convenience. (The fraction .24 in the denominator is based on 24 leap years per century.)

Each table is stored as an array, with additional attributes, and can be subset and manipulated as standard S arrays. Interpolation between calendar years is done “on the fly” by the `survexp` routine.

Some of the deficiencies, e.g., 1970 Arizona non-white, are a result of local (Mayo Clinic) conditions. The data probably exists, but we don’t have a copy it in the library.

The tables have been augmented to contain extrapolated values for 1990 and 2000. The details can be found in Mayo Clinic Biostatistics technical report 63 at <http://www.mayo.edu/hsr/techrpt.html>.

## Examples

```
survexp.uswhite <- survexp.usr[,,"white",]
```

---

`rats`

*Rat treatment data from Mantel et al*

---

## Description

Rat treatment data from Mantel et al. Three rats were chosen from each of 100 litters, one of which was treated with a drug, and then all followed for tumor incidence.

## Usage

```
rats
```

## Format

litter: litter number from 1 to 100  
rx: treatment,(1=drug, 0=control)  
time: time to tumor or last follow-up  
status: event status, 1=tumor and 0=censored  
sex: male or female

### Note

Since only 2/150 of the male rats have a tumor, most analyses use only females (odd numbered litters), e.g. Lee et al.

### Source

---

residuals.coxph	<i>Calculate Residuals for a 'coxph' Fit</i>
-----------------	--

---

**Description**

Calculates martingale, deviance, score or Schoenfeld residuals for a Cox proportional hazards model.

**Usage**

```
## S3 method for class 'coxph'
residuals(object,
  type=c("martingale", "deviance", "score", "schoenfeld",
        "dfbeta", "dfbetas", "scaledsch", "partial"),
  collapse=FALSE, weighted=FALSE, ...)
## S3 method for class 'coxph.null'
residuals(object,
  type=c("martingale", "deviance", "score", "schoenfeld"),
  collapse=FALSE, weighted=FALSE, ...)
```

**Arguments**

object	an object inheriting from class <code>coxph</code> , representing a fitted Cox regression model. Typically this is the output from the <code>coxph</code> function.
type	character string indicating the type of residual desired. Possible values are "martingale", "deviance", "score", "schoenfeld", "dfbeta", "dfbetas", and "scaledsch". Only enough of the string to determine a unique match is required.
collapse	vector indicating which rows to collapse (sum) over. In time-dependent models more than one row data can pertain to a single individual. If there were 4 individuals represented by 3, 1, 2 and 4 rows of data respectively, then <code>collapse=c(1,1,1, 2, 3,3, 4,4,4,4)</code> could be used to obtain per subject rather than per observation residuals.
weighted	if TRUE and the model was fit with case weights, then the weighted residuals are returned.
...	other unused arguments

**Value**

For martingale and deviance residuals, the returned object is a vector with one element for each subject (without `collapse`). For score residuals it is a matrix with one row per subject and one column per variable. The row order will match the input data for the original fit. For Schoenfeld residuals, the returned object is a matrix with one row for each event and one column per variable. The rows are ordered by time within strata, and an attribute `strata` is attached that contains the number of observations in each strata. The scaled Schoenfeld residuals are used in the `cox.zph` function.

The score residuals are each individual's contribution to the score vector. Two transformations of this are often more useful: `dfbeta` is the approximate change in the coefficient vector if that observation were dropped, and `dfbetas` is the approximate change in the coefficients, scaled by the standard error for the coefficients.

## NOTE

For deviance residuals, the status variable may need to be reconstructed. For score and Schoenfeld residuals, the X matrix will need to be reconstructed.

## References

## See Also

[coxph](#)

## Examples

```
fit <- coxph(Surv(start, stop, event) ~ (age + surgery)* transplant,
             data=heart)
mresid <- resid(fit, collapse=heart$tid)
```

---

`residuals.survreg`    *Compute Residuals for 'survreg' Objects*

---

## Description

This is a method for the function [residuals](#) for objects inheriting from class `survreg`.

## Usage

```
## S3 method for class 'survreg'
residuals(object, type=c("response", "deviance", "dfbeta", "dfbetas",
                          "working", "ldcase", "ldresp", "ldshape", "matrix"), rsigma=TRUE,
collapse=FALSE, weighted=FALSE, ...)
```

## Arguments

<code>object</code>	an object inheriting from class <code>survreg</code> .
<code>type</code>	type of residuals, with choices of "response", "deviance", "dfbeta", "dfbetas", "working", "ldcase", "ldresp", "ldshape", and "matrix". See the LaTeX documentation ( <a href="#">survival/doc/survival.ps.gz</a> ) for more detail.
<code>rsigma</code>	include the scale parameters in the variance matrix, when doing computations. (I can think of no good reason not to).
<code>collapse</code>	optional vector of subject groups. If given, this must be of the same length as the residuals, and causes the result to be per group residuals.
<code>weighted</code>	give weighted residuals? Normally residuals are unweighted.
<code>...</code>	other unused arguments

Value

A vector or matrix of residuals is returned. Response residuals are on the scale of the original data, working residuals are on the scale of the linear predictor, and deviance residuals are on log-likelihood scale. The dfbeta residuals are a matrix, where the *i*th row gives the approximate change in the coefficients due to the addition of subject *i*. The dfbetas matrix contains the dfbeta residuals, with each column scaled by the standard deviation of that coefficient.

The matrix type produces a matrix based on derivatives of the log-likelihood function. Let *L* be the log-likelihood, *p* be the linear predictor  $X\beta$ , and *s* be  $\log(\sigma)$ . Then the 6 columns of the matrix are *L*,  $dL/dp$ ,  $\partial^2 L/\partial p^2$ ,  $dL/ds$ ,  $\partial^2 L/\partial s^2$  and  $\partial^2 L/\partial p \partial s$ . Diagnostics based on these quantities are discussed in an article by Escobar and Meeker. The main ones are the likelihood displacement residuals for perturbation of a case weight (*ldcase*), the response value (*ldresp*), and the shape.

```
fit <- survreg(Surv(time,status) ~x, aml)
rr <- residuals(fit, type='matrix')
```

---

ridge	<i>Ridge regression</i>
-------	-------------------------

---

Description

When used in a [coxph](#) or [survreg](#) model formula, specifies a ridge regression term. The likelihood is penalised by *theta*/2 time the sum of squared coefficients. If *scale=T* the penalty is calculated for coefficients based on rescaling the predictors to have unit variance. If *df* is specified then *theta* is chosen based on an approximate degrees of freedom.

Usage

```
ridge(..., theta, df=nvar/2, eps=0.1, scale=TRUE)
```

Arguments

- |              |   |
|--------------|---|
| <i>...</i>   | predictors to be ridged                                     |
| <i>theta</i> | penalty is <i>theta</i> /2 time sum of squared coefficients |
| <i>df</i>    | Approximate degrees of freedom                              |
| <i>eps</i>   | Accuracy required for <i>df</i>                             |
| <i>scale</i> | Scale variables before applying penalty?                    |

**Value**

An object of class `coxph.penalty` containing the data and control functions.

---

strata

*Identify Stratification Variables*

---

**Description**

This is a special function used in the context of the Cox survival model. It identifies stratification variables when they appear on the right hand side of a formula.

**Usage**

```
strata(..., na.group=FALSE, shortlabel, sep=', ')
```

**Arguments**

<code>...</code>	any number of variables. All must be the same length.
<code>na.group</code>	a logical variable, if TRUE, then missing values are treated as a distinct level of each variable.
<code>shortlabel</code>	if TRUE omit variable names from resulting factor labels. The default action is to omit the names if all of the arguments are factors, and none of them was named.
<code>sep</code>	the character used to separate groups, in the created label

**Details**

The result is identical to the `interaction` function, but for the labeling of the factors (`strata` is more verbose).

**Value**

a new factor, whose levels are all possible combinations of the factors supplied as arguments.

**See Also**

[coxph](#), [interaction](#)

**Examples**

```
a <- factor(rep(1:3,4), labels="low", "medium", "high")
b <- factor(rep(1:4,3))
levels(strata(b))
levels(strata(a,b,shortlabel=TRUE))

coxph(Surv(futime, fustat) ~ age + strata(rx), data=ovarian)
```

---

summary.aareg	<i>Summarize an aareg fit</i>
---------------	-------------------------------

---

## Description

Creates the overall test statistics for an Aalen additive regression model

## Usage

```
## S3 method for class 'aareg'
summary(object, maxtime, test=c("aalen", "nrisk"), scale=1,...)
```

## Arguments

object	the result of a call to the aareg function
maxtime	truncate the input to the model at time "maxtime"
test	the relative time weights that will be used to compute the test
scale	scales the coefficients. For some data sets, the coefficients of the Aalen model will be very small (10 <sup>-4</sup> ); this simply multiplies the printed values by a constant, say 1e6, to make the printout easier to read.
...	for future methods

## Details

It is not uncommon for the very right-hand tail of the plot to have large outlying values, particularly for the standard error. The `maxtime` parameter can then be used to truncate the range so as to avoid these. This gives an updated value for the test statistics, without refitting the model.

The slope is based on a weighted linear regression to the cumulative coefficient plot, and may be a useful measure of the overall size of the effect. For instance when two models include a common variable, "age" for instance, this may help to assess how much the fit changed due to the other variables, in lieu of overlaying the two plots. (Of course the plots are often highly non-linear, so it is only a rough substitute). The slope is not directly related to the test statistic, as the latter is invariant to any monotone transformation of time.

## Value

a list is returned with the following components

table	a matrix with rows for the intercept and each covariate, and columns giving a slope estimate, the test statistic, it's standard error, the z-score and a p-value
test	the time weighting used for computing the test statistics
test.statistic	the vector of test statistics
test.var	the model based variance matrix for the test statistic
test.var2	optionally, a robust variance matrix for the test statistic
chisq	the overall test (ignoring the intercept term) for significance of any variable
n	a vector containing the number of observations, the number of unique death times used in the computation, and the total number of unique death times

summary.coxph	<i>Summary method for Cox models</i>
---------------	--------------------------------------

---

Description

Produces a summary of a fitted coxph model

Usage

```
## S3 method for class 'coxph'
summary(object, conf.int=0.95, scale=1,...)
```

Arguments

object	the result of a coxph fit
conf.int	level for computation of the confidence intervals. If set to FALSE no confidence intervals are printed
scale	vector of scale factors for the coefficients, defaults to 1. The confidence limits are for the risk change associated with one scale unit.
...	for future methods

**Value**

An object of class `summary.coxph`.

**See Also**

---

summary.survexp	<i>Summary function for a survexp object</i>
-----------------	--

---

**Description**

Returns a list containing the values of the survival at specified times.

**Usage**

```
## S3 method for class 'survexp'
summary(object, times, scale = 1, ...)
```

**Arguments**

<code>object</code>	the result of a call to the <code>survexp</code> function
<code>times</code>	vector of times; the returned matrix will contain 1 row for each time. Missing values are not allowed.
<code>scale</code>	numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale = 365.25</code> would scale the output to years.
<code>...</code>	For future methods

**Details**

A primary use of this function is to retrieve survival at fixed time points, which will be properly interpolated by the function.

**Value**

a list with the following components:

surv	the estimate of survival at time t.
time	the timepoints on the curve.
n.risk	In expected survival each subject from the data set is matched to a hypothetical person from the parent population, matched on the characteristics of the parent population. The number at risk is the number of those hypothetical subject who are still part of the calculation.

---

summary.survfit	<i>Summary of a Survival Curve</i>
-----------------	------------------------------------

---

**Description**

Returns a list containing the survival curve, confidence limits for the curve, and other information.

**Usage**

```
## S3 method for class 'survfit'
summary(object, times=, censored=FALSE, scale=1,
        extend=FALSE, rmean=getOption('survfit.rmean'), ...)
```

**Arguments**

object	the result of a call to the <code>survfit</code> function.
times	vector of times; the returned matrix will contain 1 row for each time. The vector will be sorted into increasing order; missing values are not allowed. If <code>censored=T</code> , the default <code>times</code> vector contains all the unique times in <code>fit</code> , otherwise the default <code>times</code> vector uses only the event (death) times.
censored	logical value: should the censoring times be included in the output? This is ignored if the <code>times</code> argument is present.
scale	numeric value to rescale the survival time, e.g., if the input data to <code>survfit</code> were in days, <code>scale = 365.25</code> would scale the output to years.

<code>extend</code>	logical value: if TRUE, prints information for all specified <code>times</code> , even if there are no subjects left at the end of the specified <code>times</code> . This is only valid if the <code>times</code> argument is present.
<code>rmean</code>	Show restricted mean: see <code>print.survfit</code> for details
<code>...</code>	for future methods

**Value**

a list with the following components:

<code>surv</code>	the estimate of survival at time <code>t+0</code> .
<code>time</code>	the timepoints on the curve.
<code>n.risk</code>	the number of subjects at risk at time <code>t-0</code> (but see the comments on weights in the <code>survfit</code> help file).
<code>n.event</code>	if the <code>times</code> argument is missing, then this column is the number of events that occurred at time <code>t</code> . Otherwise, it is the cumulative number of events that have occurred since the last time listed until time <code>t+0</code> .
<code>n.entered</code>	This is present only for counting process survival data. If the <code>times</code> argument is missing, this column is the number of subjects that entered at time <code>t</code> . Otherwise, it is the cumulative number of subjects that have entered since the last time listed until time <code>t</code> .
<code>n.exit.censored</code>	if the <code>times</code> argument is missing, this column is the number of subjects that left without an event at time <code>t</code> . Otherwise, it is the cumulative number of subjects that have left without an event since the last time listed until time <code>t+0</code> . This is only present for counting process survival data.
<code>std.err</code>	the standard error of the survival value.
<code>conf.int</code>	level of confidence for the confidence intervals of survival.
<code>lower</code>	lower confidence limits for the curve.
<code>upper</code>	upper confidence limits for the curve.
<code>strata</code>	indicates stratification of curve estimation. If <code>strata</code> is not NULL, there are multiple curves in the result and the <code>surv</code> , <code>time</code> , <code>n.risk</code> , etc. vectors will contain multiple curves, pasted end to end. The levels of <code>strata</code> (a factor) are the labels for the curves.
<code>call</code>	the statement used to create the <code>fit</code> object.
<code>na.action</code>	same as for <code>fit</code> , if present.
<code>table</code>	table of information that is returned from <code>print.survfit</code> function.
<code>type</code>	type of data censoring. Passed through from the <code>fit</code> object.

**See Also**

summary( survfit( Surv(futime, fustat)~rx, data=ovarian))
```

Surv

*Create a Survival Object***Description**

Create a survival object, usually used as a response variable in a model formula. Argument matching is special for this function, see Details below.

**Usage**

```
Surv(time, time2, event,
      type=c('right', 'left', 'interval', 'counting', 'interval2', 'mstate'),
      origin=0)
is.Surv(x)
```

**Arguments**

time	for right censored data, this is the follow up time. For interval data, the first argument is the starting time for the interval.
event	The status indicator, normally 0=alive, 1=dead. Other choices are TRUE/FALSE (TRUE = death) or 1/2 (2=death). For interval censored data, the status indicator is 0=right censored, 1=event at time, 2=left censored, 3=interval censored. Although unusual, the event indicator can be omitted, in which case all subjects are assumed to have an event.
time2	ending time of the interval for interval censored or counting process data only. Intervals are assumed to be open on the left and closed on the right, (start, end]. For counting process data, event indicates whether an event occurred at the end of the interval.
type	character string specifying the type of censoring. Possible values are "right", "left", "counting", "interval", "interval2" or "mstate".
origin	for counting process data, the hazard function origin. This option was intended to be used in conjunction with a model containing time dependent strata in order to align the subjects properly when they cross over from one strata to another, but it has rarely proven useful.
x	any R object.

**Details**

When the `type` argument is missing the code assumes a type based on the following rules:

- If there are two unnamed arguments, they will match `time` and `event` in that order. If there are three unnamed arguments they match `time`, `time2` and `event`.
- If the event variable is a factor then type `mstate` is assumed. Otherwise type `right` if there is no `time2` argument, and type `counting` if there is.

As a consequence the `type` argument can usually be omitted.

When the survival type is "mstate" then the status variable will be treated as a factor. The first level of the factor is taken to represent censoring and remaining ones a transition to the given state.

Interval censored data can be represented in two ways. For the first use `type = "interval"` and the codes shown above. In that usage the value of the `time2` argument is ignored unless

event=3. The second approach is to think of each observation as a time interval with  $(-\infty, t)$  for left censored,  $(t, \infty)$  for right censored,  $(t, t)$  for exact and  $(t_1, t_2)$  for an interval. This is the approach used for `type = interval2`. Infinite values can be represented either by actual infinity (`Inf`) or `NA`. The second form has proven to be the more useful one.

Presently, the only methods allowing interval censored data are the parametric models computed by `survreg` and survival curves computed by `survfit`; for both of these, the distinction between open and closed intervals is unimportant. The distinction is important for counting process data and the Cox model.

The function tries to distinguish between the use of 0/1 and 1/2 coding for censored data via the condition `if (max(status)==2)`. If 1/2 coding is used and all the subjects are censored, it will guess wrong. In any questionable case it is safer to use logical coding, e.g., `Surv(time, status==3)` would indicate that a 3 is the code for an event.

For multi-state survival (`type= "mstate"`) the status variable can have multiple levels. The first of these will stand for censoring, and the others for various event types, e.g., causes of death.

`Surv` objects can be subscripted either as a vector, e.g. `x[1:3]` using a single subscript, in which case the `drop` argument is ignored and the result will be a survival object; or as a matrix by using two subscripts. If the second subscript is missing and `drop=F` (the default), the result of the subscripting will be a `Surv` object, e.g., `x[1:3, , drop=F]`, otherwise the result will be a matrix (or vector), in accordance with the default behavior for subscripting matrices.

## Value

An object of class `Surv`. There are methods for `print`, `is.na`, and subscripting survival objects. `Surv` objects are implemented as a matrix of 2 or 3 columns that has further attributes. These include the type (left censored, right censored, counting process, etc.) and labels for the states for multi-state objects. Any attributes of the input arguments are also preserved in `inputAttributes`. This may be useful for other packages that have attached further information to data items such as labels; none of the routines in the survival package make use of these values, however.

In the case of `is.Surv`, a logical value `TRUE` if `x` inherits from class `"Surv"`, otherwise `FALSE`.

---

survConcordance

*Compute a concordance measure.*

---

## Description

This function computes the concordance between a right-censored survival time and a single continuous covariate

**Usage**

```
survConcordance(formula, data, weights, subset, na.action)
survConcordance.fit(y, x, strata, weight)
```

**Arguments**

<code>formula</code>	a formula with a survival time on the left and a single covariate on the right, along with an optional <code>strata()</code> term. The left hand term can also be a numeric vector.
<code>data</code>	a data frame
<code>weights, subset, na.action</code>	as for <code>coxph</code>
<code>x, y, strata, weight</code>	predictor, response, strata, and weight vectors for the direct call

**Details**

The `survConcordance.fit` function computes the result but does no data checking whatsoever. It is intended as a hook for other packages that wish to compute concordance, and the data has already been assembled and verified.

Concordance is defined as  $\Pr(\text{agreement})$  for any two randomly chosen observations, where in this case agreement means that the observation with the shorter survival time of the two also has the larger risk score. The predictor (or risk score) will often be the result of a Cox model or other regression.

For continuous covariates concordance is equivalent to Kendall's tau, and for logistic regression is equivalent to the area under the ROC curve. A value of 1 signifies perfect agreement, .6-.7 is a common result for survival data, .5 is an agreement that is no better than chance, and .3-.4 is the performance of some stock market analysts.

The computation involves all  $n(n-1)/2$  pairs of data points in the sample. For survival data, however, some of the pairs are incomparable. For instance a pair of times (5+, 8), the first being a censored value. We do not know whether the first survival time is greater than or less than the second. Among observations that are comparable, pairs may also be tied on survival time (but only if both are uncensored) or on the predictor. The final concordance is  $(\text{agree} + \text{tied}/2)/(\text{agree} + \text{disagree} + \text{tied})$ .

There is, unfortunately, one aspect of the formula above that is unclear. Should the count of ties include observations that are tied on survival time  $y$ , tied on the predictor  $x$ , or both? By default the concordance only counts ties in  $x$ , treating tied survival times as incomparable; this agrees with the AUC calculation used in logistic regression. The Goodman-Kruskal Gamma statistic is  $(\text{agree} - \text{disagree})/(\text{agree} + \text{disagree})$ , ignoring ties. It ranges from -1 to +1 similar to a correlation coefficient. Kendall's tau uses ties of both types. All of the components are returned in the result, however, so people can compute other combinations if interested. (If two observations have the same survival and the same  $x$ , they are counted in the tied survival time category).

The algorithm is based on a balanced binary tree, which allows the computation to be done in  $O(n \log n)$  time.

**Value**

an object containing the concordance, followed by the number of pairs that agree, disagree, are tied, and are not comparable.

**See Also**

summary.coxph

**Examples**

```

survConcordance(Surv(time, status) ~age, data=lung)

options(na.action=na.exclude)
fit <- coxph(Surv(time, status) ~ ph.ecog + age + sex, lung)
survConcordance(Surv(time, status) ~predict(fit), lung)
## Not run:
  n=227 (1 observations deleted due to missing values)
Concordance= 0.6371102 , Gamma= 0.2759638
concordant discordant tied risk tied time
      12544      7117      126      28

## End(Not run)

```

survdiff

*Test Survival Curve Differences***Description**

Tests if there is a difference between two or more survival curves using the  $G^p$  family of tests, or for a single curve against a known alternative.

**Usage**

```
survdiff(formula, data, subset, na.action, rho=0)
```

**Arguments**

formula	a formula expression as for other survival models, of the form <code>Surv(time, status) ~ predictors</code> . For a one-sample test, the predictors must consist of a single <code>offset(sp)</code> term, where <code>sp</code> is a vector giving the survival probability of each subject. For a k-sample test, each unique combination of predictors defines a subgroup. A <code>strata</code> term may be used to produce a stratified test. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the <code>strata</code> function with its <code>na.group=T</code> argument.
data	an optional data frame in which to interpret the variables occurring in the formula.
subset	expression indicating which subset of the rows of data should be used in the fit. This can be a logical vector (which is replicated to have length equal to the number of observations), a numeric vector indicating which observation numbers are to be included (or excluded if negative), or a character vector of row names to be included. All observations are included by default.
na.action	a missing-data filter function. This is applied to the <code>model.frame</code> after any subset argument has been used. Default is <code>options()\$na.action</code> .
rho	a scalar parameter that controls the type of test.

**Value**

a list with components:

<code>n</code>	the number of subjects in each group.
<code>obs</code>	the weighted observed number of events in each group. If there are strata, this will be a matrix with one column per stratum.
<code>exp</code>	the weighted expected number of events in each group. If there are strata, this will be a matrix with one column per stratum.
<code>chisq</code>	the chisquare statistic for a test of equality.
<code>var</code>	the variance matrix of the test.
<code>strata</code>	optionally, the number of subjects contained in each stratum.

**METHOD**

This function implements the G-rho family of Harrington and Fleming (1982), with weights on each death of  $S(t)^{\rho}$ , where  $S(t)$  is the Kaplan-Meier estimate of survival. With `rho = 0` this is the log-rank or Mantel-Haenszel test, and with `rho = 1` it is equivalent to the Peto & Peto modification of the Gehan-Wilcoxon test.

If the right hand side of the formula consists only of an offset term, then a one sample test is done. To cause missing values in the predictors to be treated as a separate group, rather than being omitted, use the `factor` function with its `exclude` argument.

**References**

Harrington, D. P. and Fleming, T. R. (1982). A class of rank test procedures for censored survival data. *Biometrika* **69**, 553-566.

**Examples**

```
## Two-sample test
survdif(Surv(futime, fustat) ~ rx, data=ovarian)

## Stratified 7-sample test

survdif(Surv(time, status) ~ pat.karno + strata(inst), data=lung)

## Expected survival for heart transplant patients based on
## US mortality tables
expect <- survexp(futime ~ ratetable(age=(accept.dt - birth.dt),
  sex=1, year=accept.dt, race="white"), jasa, cohort=FALSE,
  ratetable=survexp.usr)
## actual survival is much worse (no surprise)
survdif(Surv(jasa$futime, jasa$fustat) ~ offset(expect))
```

survexp

*Compute Expected Survival***Description**

Returns either the expected survival of a cohort of subjects, or the individual expected survival for each subject.

**Usage**

```
survexp(formula, data, weights, subset, na.action, rmap, times,
        method=c("ederer", "hakulinen", "conditional", "individual.h",
                  "individual.s"),
        cohort=TRUE, conditional=FALSE,
        ratetable=survival::survexp.us, scale=1,
        se.fit, model=FALSE, x=FALSE, y=FALSE)
```

**Arguments**

<code>formula</code>	formula object. The response variable is a vector of follow-up times and is optional. The predictors consist of optional grouping variables separated by the <code>+</code> operator (as in <code>survfit</code> ), and is often <code>~1</code> , i.e., expected survival for the entire group.
<code>data</code>	data frame in which to interpret the variables named in the <code>formula</code> , <code>subset</code> and <code>weights</code> arguments.
<code>weights</code>	case weights. This is most useful when conditional survival for a known population is desired, e.g., the data set would contain all unique age/sex combinations and the weights would be the proportion of each.
<code>subset</code>	expression indicating a subset of the rows of <code>data</code> to be used in the fit.
<code>na.action</code>	function to filter missing data. This is applied to the model frame after <code>subset</code> has been applied. Default is <code>options()\$na.action</code> .
<code>rmap</code>	an optional list that maps data set names to the <code>ratetable</code> names. See the details section below.
<code>times</code>	vector of follow-up times at which the resulting survival curve is evaluated. If absent, the result will be reported for each unique value of the vector of times supplied in the response value of the <code>formula</code> .
<code>method</code>	computational method for the creating the survival curves. The <code>individual</code> option does not create a curve, rather it retrieves the predicted survival <code>individual.s</code> or cumulative hazard <code>individual.h</code> for each subject. The default is to use <code>method='ederer'</code> if the formula has no response, and <code>method='hakulinen'</code> otherwise.
<code>cohort</code>	logical value. This argument has been superseded by the <code>method</code> argument. To maintain backwards compatability, if is present and <code>TRUE</code> , it implies <code>method='individual.s'</code> .
<code>conditional</code>	logical value. This argument has been superseded by the <code>method</code> argument. To maintain backwards compatability, if it is present and <code>TRUE</code> it implies <code>method='conditional'</code> .

<code>ratetable</code>	a table of event rates, such as <code>survexp.mn</code> , or a fitted Cox model. Note the <code>survival::</code> prefix in the default argument is present to avoid the (rare) case of a user who expects the default table but just happens to have an object named "survexp.us" in their own directory.
<code>scale</code>	numeric value to scale the results. If <code>ratetable</code> is in units/day, <code>scale = 365.25</code> causes the output to be reported in years.
<code>se.fit</code>	compute the standard error of the predicted survival. This argument is currently ignored. Standard errors are not a defined concept for population rate tables (they are treated as coming from a complete census), and for Cox models the calculation is hard. Despite good intentions standard errors for this latter case have not been coded and validated.
<code>model, x, y</code>	flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.

## Details

Individual expected survival is usually used in models or testing, to 'correct' for the age and sex composition of a group of subjects. For instance, assume that birth date, entry date into the study, sex and actual survival time are all known for a group of subjects. The `survexp.us` population tables contain expected death rates based on calendar year, sex and age. Then

```
haz <- survexp(fu.time ~ 1, data=mydata,
               rmap = list(year=entry.dt, age=(birth.dt-entry.dt)),
               method='individual.h'))
```

gives for each subject the total hazard experienced up to their observed death time or last follow-up time (variable `fu.time`) This probability can be used as a rescaled time value in models:

```
glm(status ~ 1 + offset(log(haz)), family=poisson)
glm(status ~ x + offset(log(haz)), family=poisson)
```

In the first model, a test for `intercept=0` is the one sample log-rank test of whether the observed group of subjects has equivalent survival to the baseline population. The second model tests for an effect of variable `x` after adjustment for age and sex.

The `ratetable` being used may have different variable names than the user's data set, this is dealt with by the `rmap` argument. The rate table for the above calculation was `survexp.us`, a call to `summary{survexp.us}` reveals that it expects to have variables `age` = age in days, `sex`, and `year` = the date of study entry, we create them in the `rmap` line. The `sex` variable was not mapped, therefore the function assumes that it exists in `mydata` in the correct format. (Note: for factors such as `sex`, the program will match on any unique abbreviation, ignoring case.)

Cohort survival is used to produce an overall survival curve. This is then added to the Kaplan-Meier plot of the study group for visual comparison between these subjects and the population at large. There are three common methods of computing cohort survival. In the "exact method" of Ederer the cohort is not censored, for this case no response variable is required in the formula. Hakulinen recommends censoring the cohort at the anticipated censoring time of each patient, and Verheul recommends censoring the cohort at the actual observation time of each patient. The last of these is the conditional method. These are obtained by using the respective time values as the follow-up time or response in the formula.

**Value**

if `cohort=TRUE` an object of class `survexp`, otherwise a vector of per-subject expected survival values. The former contains the number of subjects at risk and the expected survival for the cohort at each requested time. The cohort survival is the hypothetical survival for a cohort of subjects enrolled from the population at large, but matching the data set on the factors found in the rate table.

---

survexp.fit

*Compute Expected Survival*

---

**Description**

Compute expected survival times.

## Usage

```
survexp.fit(group, x, y, times, death, ratetable)
```

## Arguments

group	if there are multiple survival curves this identifies the group, otherwise it is a constant. Must be an integer.
x	A matrix whose columns match the dimensions of the <code>ratetable</code> , in the correct order.
y	the follow up time for each subject.
times	the vector of times at which a result will be computed.
death	a logical value, if <code>TRUE</code> the conditional survival is computed, if <code>FALSE</code> the cohort survival is computed. See <a href="#">survexp</a> for more details.
ratetable	a rate table, such as <code>survexp.uswhite</code> .

## Details

For conditional survival `y` must be the time of last follow-up or death for each subject. For cohort survival it must be the potential censoring time for each subject, ignoring death.

For an exact estimate `times` should be a superset of `y`, so that each subject at risk is at risk for the entire sub-interval of time. For a large data set, however, this can use an inordinate amount of storage and/or compute time. If the `times` spacing is more coarse than this, an actuarial approximation is used which should, however, be extremely accurate as long as all of the returned values are  $> .99$ .

For a subgroup of size 1 and `times > y`, the conditional method reduces to  $\exp(-h)$  where  $h$  is the expected cumulative hazard for the subject over his/her observation time. This is used to compute individual expected survival.

## Value

A list containing the number of subjects and the expected survival(s) at each time point. If there are multiple groups, these will be matrices with one column per group.

## Warning

Most users will call the higher level routine `survexp`. Consequently, this function has very few error checks on its input arguments.

---

`survfit`*Create survival curves*

---

## Description

This function creates survival curves from either a formula (e.g. the Kaplan-Meier), a previously fitted Cox model, or a previously fitted accelerated failure time model.

## Usage

```
survfit(formula, ...)
```

## Arguments

<code>formula</code>	either a formula or a previously fitted model
<code>...</code>	other arguments to the specific method

## Details

A survival curve is based on a tabulation of the number at risk and number of events at each unique death time. When time is a floating point number the definition of "unique" is subject to interpretation. The code uses `factor()` to define the set. For further details see the documentation for the appropriate method, i.e., `?survfit.formula` or `?survfit.coxph`.

## Value

An object of class `survfit` containing one or more survival curves.

## Note

Older releases of the code also allowed the specification for a single curve to omit the right hand of the formula, i.e., `~ 1`. Handling this case required some non-standard and fairly fragile manipulations, and this case is no longer supported.

## Author(s)

Terry Therneau

survfit.coxph

*Compute a Survival Curve from a Cox model***Description**

Computes the predicted survivor function for a Cox proportional hazards model.

**Usage**

```
## S3 method for class 'coxph'
survfit(formula, newdata,
        se.fit=TRUE, conf.int=.95,
        individual=FALSE,
        type,vartype,
        conf.type=c("log", "log-log", "plain", "none"), censor=TRUE, id,
        na.action=na.pass, ...)
```

**Arguments**

formula	A coxph object.
newdata	<p>a data frame with the same variable names as those that appear in the coxph formula. It is also valid to use a vector, if the data frame would consist of a single row.</p> <p>The curve(s) produced will be representative of a cohort whose covariates correspond to the values in newdata. Default is the mean of the covariates used in the coxph fit.</p>
individual	<p>This argument has been superseded by the id argument and is present only for backwards compatability. A logical value indicating whether each row of newdata represents a distinct individual (FALSE, the default), or if each row of the data frame represents different time epochs for only one individual (TRUE). In the former case the result will have one curve for each row in newdata, in the latter only a single curve will be produced.</p>
conf.int	the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.
se.fit	a logical value indicating whether standard errors should be computed. Default is TRUE.
type,vartype	<p>a character string specifying the type of survival curve. Possible values are "aalen", "efron", or "kalbfleisch-prentice" (only the first two characters are necessary). The default is to match the computation used in the Cox model. The Nelson-Aalen-Breslow estimate for ties='breslow', the Efron estimate for ties='efron' and the Kalbfleisch-Prentice estimate for a discrete time model ties='exact'. Variance estimates are the Aalen-Link-Tsiatis, Efron, and Greenwood. The default will be the Efron estimate for ties='efron' and the Aalen estimate otherwise.</p>
conf.type	<p>One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals <math>\text{curve} \pm k * \text{se}(\text{curve})</math>, where k is determined from</p>

	<code>conf.int.</code> The log option calculates intervals based on the cumulative hazard or <code>log(survival)</code> . The last option bases intervals on the log hazard or <code>log(-log(survival))</code> .
<code>censor</code>	if FALSE time points at which there are no events (only censoring) are not included in the result.
<code>id</code>	optional variable name of subject identifiers. If this is present, then each group of rows with the same subject <code>id</code> represents the covariate path through time of a single subject, and the result will contain one curve per subject. If the <code>coxph</code> fit had strata then that must also be specified in <code>newdata</code> . If missing, then each individual row of <code>newdata</code> is presumed to represent a distinct subject and there will be <code>nrow(newdata)</code> times the number of strata curves in the result (one for each strata/subject combination). <code>result</code> .
<code>na.action</code>	the <code>na.action</code> to be used on the <code>newdata</code> argument
<code>...</code>	for future methods

## Details

Serious thought has been given to removing the default value for `newdata`, which is to use a single "psuedo" subject with covariate values equal to the means of the data set, since the resulting curve(s) almost never make sense. It remains due to an unwarranted attachment to the option shown by some users and by other packages. Two particularly egregious examples are factor variables and interactions. Suppose one were studying interspecies transmission of a virus, and the data set has a factor variable with levels ("pig", "chicken") and about equal numbers of observations for each. The "mean" covariate level will be 1/2 – is this a flying pig? As to interactions assume data with sex coded as 0/1, ages ranging from 50 to 80, and a model with `age*sex`. The "mean" value for the `age:sex` interaction term will be about 30, a value that does not occur in the data. Users are strongly advised to use the `newdata` argument.

When the original model contains time-dependent covariates, then the path of that covariate through time needs to be specified in order to obtain a predicted curve. This requires `newdata` to contain multiple lines for each hypothetical subject which gives the covariate values, time interval, and strata for each line (a subject can change strata), along with an `id` variable which demarks which rows belong to each subject. The time interval must have the same (start, stop, status) variables as the original model: although the status variable is not used and thus can be set to a dummy value of 0 or 1, it is necessary for the variables to be recognized as a `Surv` object. Last, although predictions with a time-dependent covariate path can be useful, it is very easy to create a prediction that is senseless. Users are encouraged to seek out a text that discusses the issue in detail.

When a model contains strata but no time-dependent covariates the user of this routine has a choice. If `newdata` argument does not contain strata variables then the returned object will be a matrix of survival curves with one row for each strata in the model and one column for each row in `newdata`. (This is the historical behavior of the routine.) If `newdata` does contain strata variables, then the result will contain one curve per row of `newdata`, based on the indicated stratum of the original model. In the rare case of a model with strata by covariate interactions the strata variable must be included in `newdata`, the routine does not allow it to be omitted (predictions become too confusing). (Note that the model `Surv(time, status) ~ age*strata(sex)` expands internally to `strata(sex) + age:sex`; the sex variable is needed for the second term of the model.)

When all the coefficients are zero, the Kalbfleisch-Prentice estimator reduces to the Kaplan-Meier, the Aalen estimate to the exponential of Nelson's cumulative hazard estimate, and the Efron estimate to the Fleming-Harrington estimate of survival. The variances of the curves from a Cox model are larger than these non-parametric estimates, however, due to the variance of the coefficients.

See [survfit](#) for more details about the counts (number of events, number at risk, etc.)

---

survfit.formula	<i>Compute a Survival Curve for Censored Data</i>
-----------------	---

---

## Description

Computes an estimate of a survival curve for censored data using either the Kaplan-Meier or the Fleming-Harrington method. For competing risks data it computes the cumulative incidence curve.

## Usage

```

## S3 method for class 'formula'
survfit(formula, data, weights, subset, na.action,
        etype, id, istate, ...)

```

## Arguments

formula	a formula object, which must have a <code>Surv</code> object as the response on the left of the <code>~</code> operator and, if desired, terms separated by <code>+</code> operators on the right. One of the terms may be a <code>strata</code> object. For a single survival curve the right hand side should be <code>~ 1</code> .
data	a data frame in which to interpret the variables named in the formula, <code>subset</code> and <code>weights</code> arguments.
weights	The weights must be nonnegative and it is strongly recommended that they be strictly positive, since zero weights are ambiguous, compared to use of the <code>subset</code> argument.
subset	expression saying that only a subset of the rows of the data should be used in the fit.
na.action	a missing-data filter function, applied to the model frame, after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
etype	a variable giving the type of event. This has been superseded by multi-state <code>Surv</code> objects; see example below.

<code>id</code>	identifies individual subjects, when a given person can have multiple lines of data.
<code>istate</code>	for multi-state models, identifies the initial state of each subject
<code>...</code>	The following additional arguments are passed to internal functions called by <code>survfit</code> .
<b>type</b>	a character string specifying the type of survival curve. Possible values are "kaplan-meier", "fleming-harrington" or "fh2" if a formula is given. This is ignored for competing risks or when the Turnbull estimator is used.
<b>error</b>	a character string specifying the error. Possible values are "greenwood" for the Greenwood formula or "tsiatis" or "aalen" for the Tsiatis/Aalen formula, or "robust" for a robust variance. The last of these is assumed if non-integer case weights are provided.
<b>conf.type</b>	One of "none", "plain", "log" (the default), or "log-log". Only enough of the string to uniquely identify it is necessary. The first option causes confidence intervals not to be generated. The second causes the standard intervals $\text{curve} \pm k * \text{se}(\text{curve})$ , where $k$ is determined from <code>conf.int</code> . The log option calculates intervals based on the cumulative hazard or $\log(\text{survival})$ . The last option bases intervals on the log hazard or $\log(-\log(\text{survival}))$ .
<b>conf.lower</b>	a character string to specify modified lower limits to the curve, the upper limit remains unchanged. Possible values are "usual" (unmodified), "peto", and "modified". The modified lower limit is based on an "effective n" argument. The confidence bands will agree with the usual calculation at each death time, but unlike the usual bands the confidence interval becomes wider at each censored observation. The extra width is obtained by multiplying the usual variance by a factor $m/n$ , where $n$ is the number currently at risk and $m$ is the number at risk at the last death time. (The bands thus agree with the un-modified bands at each death time.) This is especially useful for survival curves with a long flat tail. The Peto lower limit is based on the same "effective n" argument as the modified limit, but also replaces the usual Greenwood variance term with a simple approximation. It is known to be conservative.
<b>start.time</b>	numeric value specifying a time to start calculating survival information. The resulting curve is the survival conditional on surviving to <code>start.time</code> .
<b>conf.int</b>	the level for a two-sided confidence interval on the survival curve(s). Default is 0.95.
<b>se.fit</b>	a logical value indicating whether standard errors should be computed. Default is TRUE.

## Details

The estimates used are the Kalbfleisch-Prentice (Kalbfleisch and Prentice, 1980, p.86) and the Tsiatis/Link/Breslow, which reduce to the Kaplan-Meier and Fleming-Harrington estimates, respectively, when the weights are unity.

The Greenwood formula for the variance is a sum of terms  $d/(n*(n-m))$ , where  $d$  is the number of deaths at a given time point,  $n$  is the sum of weights for all individuals still at risk at that time, and  $m$  is the sum of weights for the deaths at that time. The justification is based on a binomial argument when weights are all equal to one; extension to the weighted case is ad hoc. Tsiatis (1981) proposes a sum of terms  $d/(n*n)$ , based on a counting process argument which includes the weighted case.

The two variants of the F-H estimate have to do with how ties are handled. If there were 3 deaths out of 10 at risk, then the first increments the hazard by 3/10 and the second by 1/10 + 1/9 + 1/8. For the first method  $S(t) = \exp(H)$ , where  $H$  is the Nelson-Aalen cumulative hazard estimate, whereas the `fh2` method will give results  $S(t)$  results closer to the Kaplan-Meier.

When the data set includes left censored or interval censored data (or both), then the EM approach of Turnbull is used to compute the overall curve. When the baseline method is the Kaplan-Meier, this is known to converge to the maximum likelihood estimate.

The cumulative incidence curve is an alternative to the Kaplan-Meier for competing risks data. For instance, in patients with MGUS, conversion to an overt plasma cell malignancy occurs at a nearly constant rate among those still alive. A Kaplan-Meier estimate, treating death due to other causes as censored, gives a 20 year cumulate rate of 33% for the 241 early patients of Kyle. This estimates the incidence of conversion if all other causes of death were removed, which is an unrealistic assumption given the mean starting age of 63 and a median follow up of over 21 years.

The CI estimate, on the other hand, estimates the total number of conversions that will actually occur. Because the population is older, this is much smaller than the KM, 22% at 20 years for Kyle's data. If there were no censoring, then  $CI(t)$  could very simply be computed as total number of patients with progression by time  $t$  divided by the sample size  $n$ .

## Value

an object of class "survfit". See `survfit.object` for details. Methods defined for `survfit` objects are `print`, `plot`, `lines`, and `points`.

---

survfit.object

*Survival Curve Object*

---

## Description

This class of objects is returned by the `survfit` class of functions to represent a fitted survival curve.

Objects of this class have methods for the functions `print`, `summary`, `plot`, `points` and `lines`. The `print.survfit` method does more computation than is typical for a print method and is documented on a separate page. Class of objects that represent a fitted survival curve.

**Arguments**

<code>n</code>	total number of subjects in each curve.
<code>time</code>	the time points at which the curve has a step.
<code>n.risk</code>	the number of subjects at risk at <code>t</code> .
<code>n.event</code>	the number of events that occur at time <code>t</code> .
<code>n.enter</code>	for counting process data only, the number of subjects that enter at time <code>t</code> .
<code>n.censor</code>	for counting process data only, the number of subjects who exit the risk set, without an event, at time <code>t</code> . (For right censored data, this number can be computed from the successive values of the number at risk).
<code>surv</code>	the estimate of survival at time <code>t+0</code> . This may be a vector or a matrix.
<code>std.err</code>	the standard error of the cumulative hazard or $-\log(\text{survival})$ .
<code>upper</code>	upper confidence limit for the survival curve.
<code>lower</code>	lower confidence limit for the survival curve.
<code>strata</code>	if there are multiple curves, this component gives the number of elements of the <code>time</code> etc. vectors corresponding to the first curve, the second curve, and so on. The names of the elements are labels for the curves.
<code>start.time</code>	the value specified for the <code>start.time</code> argument, if it was used in the call.
<code>n.all</code>	for counting process data, and any time that the <code>start.time</code> argument was used, this contains the total number of observations that were available. Not all may have been used in creating the curve, in which case this value will be larger than <code>n</code> above. of observations that were available
<code>conf.type</code>	the approximation used to compute the confidence limits.
<code>conf.int</code>	the level of the confidence limits, e.g. 90 or 95%.
<code>na.action</code>	the returned value from the <code>na.action</code> function, if any. It will be used in the printout of the curve, e.g., the number of observations deleted due to missing values.
<code>call</code>	an image of the call that produced the object.
<code>type</code>	type of survival censoring.

**Structure**

The following components must be included in a legitimate `survfit` object.

**Subscripts**

Survfit objects that contain multiple survival curves can be subscripted. This is most often used to plot a subset of the curves. Usually a single subscript will be used. In one particular case – survival curves for multiple covariate values, from a Cox model that includes a `strata` statement – there is a matrix of curves and 2 subscripts may be used. (In this case `summary.survfit` will also print the data as a matrix).

---

survfitcoxph.fit     *A direct interface to the ‘computational engine’ of survfit.coxph*

---

## Description

This program is mainly supplied to allow other packages to invoke the survfit.coxph function at a ‘data’ level rather than a ‘user’ level. It does no checks on the input data that is provided, which can lead to unexpected errors if that data is wrong.

## Usage

```
survfitcoxph.fit(y, x, wt, x2, risk, newrisk, strata, se.fit, survtype,
vartype, varmat, id, y2, strata2, unlist=TRUE)
```

## Arguments

y	the response variable used in the Cox model. (Missing values removed of course.)
x	covariate matrix used in the Cox model
wt	weight vector for the Cox model. If the model was unweighted use a vector of 1s.
x2	matrix describing the hypothetical subjects for which a curve is desired. Must have the same number of columns as x.
risk	the risk score $\exp(X \beta)$ from the fitted Cox model. If the model had an offset, include it in the argument to exp.
newrisk	risk scores for the hypothetical subjects
strata	strata variable used in the Cox model. This will be a factor.
se.fit	if TRUE the standard errors of the curve(s) are returned
survtype	1=Kalbfleish-Prentice, 2=Nelson-Aalen, 3=Efron. It is usual to match this to the approximation for ties used in the coxph model: KP for ‘exact’, N-A for ‘breslow’ and Efron for ‘efron’.
vartype	1=Greenwood, 2=Aalen, 3=Efron
varmat	the variance matrix of the coefficients
id	optional; if present and not NULL this should be a vector of identifiers of length <code>nrow(x2)</code> . A non-null value signifies that x2 contains time dependent co-variates, in which case this identifies which rows of x2 go with each subject.
y2	survival times, for time dependent prediction. It gives the time range (time1,time2] for each row of x2. Note: this must be a Surv object and thus contains a status indicator, which is never used in the routine, however.
strata2	vector of strata indicators for x2. This must be a factor.
unlist	if FALSE the result will be a list with one element for each strata. Otherwise the strata are “unpacked” into the form found in a survfit object.

## Value

a list containing nearly all the components of a survfit object. All that is missing is to add the confidence intervals, the type of the original model’s response (as in a coxph object), and the class.

**Note**

The source code for for both this function and `survfit.coxph` is written using `noweb`. For complete documentation see the `inst/sourcecode.pdf` file.

survobrien	<i>O'Brien's Test for Association of a Single Variable with Survival</i>
------------	--

---

**Description**

Peter O'Brien's test for association of a single variable with survival This test is proposed in Biometrics, June 1978.

**Usage**

```
survobrien(formula, data, subset, na.action, transform)
```

**Arguments**

<code>formula</code>	a valid formula for a cox model.
<code>data</code>	a <code>data.frame</code> in which to interpret the variables named in the <code>formula</code> , or in the <code>subset</code> and the <code>weights</code> argument.
<code>subset</code>	expression indicating which subset of the rows of data should be used in the fit. All observations are included by default.
<code>na.action</code>	a missing-data filter function. This is applied to the <code>model.frame</code> after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
<code>transform</code>	the transformation function to be applied at each time point. The default is O'Brien's suggestion $\text{logit}(tr)$ where $tr = (\text{rank}(x) - 1/2) / \text{length}(x)$ is the rank shifted to the range 0-1 and $\text{logit}(x) = \log(x/(1-x))$ is the logit transform.

**Value**

a new data frame. The response variables will be column names returned by the `Surv` function, i.e., "time" and "status" for simple survival data, or "start", "stop", "status" for counting process data. Each individual event time is identified by the value of the variable `.strata..` Other variables retain their original names. If a predictor variable is a factor or is protected with `I()`, it is retained as is. Other predictor variables have been replaced with time-dependent logit scores.

The new data frame will have many more rows than the original data, approximately the original number of rows \* number of deaths/2.

## Method

A time-dependent cox model can now be fit to the new data. The univariate statistic, as originally proposed, is equivalent to single variable score tests from the time-dependent model. This equivalence is the rationale for using the time dependent model as a multivariate extension of the original paper.

In O'Brien's method, the x variables are re-ranked at each death time. A simpler method, proposed by Prentice, ranks the data only once at the start. The results are usually similar.

## Note

A prior version of the routine returned new time variables rather than a strata. Unfortunately, that strategy does not work if the original formula has a strata statement. This new data set will be the same size, but the `coxph` routine will process it slightly faster.

## Examples

```
xx <- survobrien(Surv(futime, fustat) ~ age + factor(rx) + I(ecog.ps),
  data=ovarian)
coxph(Surv(time, status) ~ age + strata(.strata.), data=xx)
```

---

survreg

*Regression for a Parametric Survival Model*

---

## Description

Fit a parametric survival regression model. These are location-scale models for an arbitrary transform of the time variable; the most common cases use a log transformation, leading to accelerated failure time models.

## Usage

```
survreg(formula, data, weights, subset,
  na.action, dist="weibull", init=NULL, scale=0,
  control, parms=NULL, model=FALSE, x=FALSE,
  y=TRUE, robust=FALSE, score=FALSE, ...)
```

## Arguments

<code>formula</code>	a formula expression as for other regression models. The response is usually a survival object as returned by the <code>Surv</code> function. See the documentation for <code>Surv</code> , <code>lm</code> and <code>formula</code> for details.
<code>data</code>	a data frame in which to interpret the variables named in the <code>formula</code> , <code>weights</code> or the <code>subset</code> arguments.
<code>weights</code>	optional vector of case weights
<code>subset</code>	subset of the observations to be used in the fit
<code>na.action</code>	a missing-data filter function, applied to the <code>model.frame</code> , after any <code>subset</code> argument has been used. Default is <code>options()\$na.action</code> .
<code>dist</code>	assumed distribution for <code>y</code> variable. If the argument is a character string, then it is assumed to name an element from <a href="#">survreg.distributions</a> . These include "weibull", "exponential", "gaussian", "logistic", "lognormal" and "loglogistic". Otherwise, it is assumed to be a user defined list conforming to the format described in <a href="#">survreg.distributions</a> .
<code>parms</code>	a list of fixed parameters. For the t-distribution for instance this is the degrees of freedom; most of the distributions have no parameters.
<code>init</code>	optional vector of initial values for the parameters.
<code>scale</code>	optional fixed value for the scale. If set to $\leq 0$ then the scale is estimated.
<code>control</code>	a list of control values, in the format produced by <a href="#">survreg.control</a> . The default value is <code>survreg.control()</code>
<code>model, x, y</code>	flags to control what is returned. If any of these is true, then the model frame, the model matrix, and/or the vector of response times will be returned as components of the final result, with the same names as the flag arguments.
<code>score</code>	return the score vector. (This is expected to be zero upon successful convergence.)
<code>robust</code>	Use robust 'sandwich' standard errors, based on independence of individuals if there is no <code>cluster()</code> term in the formula, based on independence of clusters if there is.
<code>...</code>	other arguments which will be passed to <code>survreg.control</code> .

## Value

an object of class `survreg` is returned.

survreg.control      *Package options for survreg and coxph*

---

## Description

This function checks and packages the fitting options for [survreg](#)

## Usage

```
survreg.control(maxiter=30, rel.tolerance=1e-09,
  toler.chol=1e-10, iter.max, debug=0, outer.max=10)
```

## Arguments

maxiter	maximum number of iterations
rel.tolerance	relative tolerance to declare convergence
toler.chol	Tolerance to declare Cholesky decomposition singular
iter.max	same as maxiter
debug	print debugging information
outer.max	maximum number of outer iterations for choosing penalty parameters

## Value

A list with the same elements as the input

## See Also

[survreg](#)

---

survreg.distributions

*Parametric Survival Distributions*

---

## Description

List of distributions for accelerated failure models. These are location-scale families for some transformation of time. The entry describes the cdf  $F$  and density  $f$  of a canonical member of the family.

## Usage

```
survreg.distributions
```

## Format

There are two basic formats, the first defines a distribution de novo, the second defines a new distribution in terms of an old one.

name:	name of distribution
variance:	function(parms) returning the variance (currently unused)
init(x,weights,...):	Function returning an initial estimate of the mean and variance (used for initial values in the iteration)
density(x,parms):	Function returning a matrix with columns $F$ , $1 - F$ , $f$ , $f'/f$ , $f''/f$
quantile(p,parms):	Quantile function
scale:	Optional fixed value for the scale parameter
parms:	Vector of default values and names for any additional parameters
deviance(y,scale,parms):	Function returning the deviance for a saturated model; used only for deviance residuals.

and to define one distribution in terms of another

name:	name of distribution
dist:	name of parent distribution
trans:	transformation (eg log)
dtrans:	derivative of transformation
itrans:	inverse of transformation
scale:	Optional fixed value for scale parameter

## Details

There are four basic distributions: `extreme`, `gaussian`, `logistic` and `t`. The last three are parametrised in the same way as the distributions already present in R. The extreme value cdf is

$$F = 1 - e^{-e^t}.$$

When the logarithm of survival time has one of the first three distributions we obtain respectively `weibull`, `lognormal`, and `loglogistic`. The location-scale parameterizaion of a Weibull distribution found in `survreg` is not the same as the parameterization of `rweibull`.

The other predefined distributions are defined in terms of these. The exponential and rayleigh distributions are Weibull distributions with fixed scale of 1 and 0.5 respectively, and loggaussian is a synonym for lognormal.

For speed parts of the three most commonly used distributions are hardcoded in C; for this reason the elements of `survreg.distributions` with names of "Extreme value", "Logistic" and "Gaussian" should not be modified. (The order of these in the list is not important, recognition is by name.) As an alternative to modifying `survreg.distributions` a new distribution can be specified as a separate list. This is the preferred method of addition and is illustrated below.

### Examples

```
# time transformation
survreg(Surv(time, status) ~ ph.ecog + sex, dist='weibull', data=lung)
# change the transformation to work in years
# intercept changes by log(365), everything else stays the same
my.weibull <- survreg.distributions$weibull
my.weibull$trans <- function(y) log(y/365)
my.weibull$itrans <- function(y) 365*exp(y)
survreg(Surv(time, status) ~ ph.ecog + sex, lung, dist=my.weibull)

# Weibull parametrisation
y<-rweibull(1000, shape=2, scale=5)
survreg(Surv(y)~1, dist="weibull")
# survreg scale parameter maps to 1/shape, linear predictor to log(scale)

# Cauchy fit
mycauchy <- list(name='Cauchy',
  init= function(x, weights, ...)
    c(median(x), mad(x)),
  density= function(x, parms) {
    temp <- 1/(1 + x^2)
    cbind(.5 + atan(x)/pi, .5+ atan(-x)/pi,
      temp/pi, -2 *x*temp, 2*temp*(4*x^2*temp -1))
  },
  quantile= function(p, parms) tan((p-.5)*pi),
  deviance= function(...) stop('deviance residuals not defined')
)
survreg(Surv(log(time), status) ~ ph.ecog + sex, lung, dist=mycauchy)
```

---

survreg.object

*Parametric Survival Model Object*

---

### Description

This class of objects is returned by the `survreg` function to represent a fitted parametric survival model. Objects of this class have methods for the functions `print`, `summary`, `predict`, and `residuals`.

COMPONENTS

The following components must be included in a legitimate `survreg` object.

- coefficients** the coefficients of the `linear.predictors`, which multiply the columns of the model matrix. It does not include the estimate of error (sigma). The names of the coefficients are the names of the single-degree-of-freedom effects (the columns of the model matrix). If the model is over-determined there will be missing values in the coefficients corresponding to non-estimable coefficients.
- icoef** coefficients of the baseline model, which will contain the intercept and `log(scale)`, or multiple scale factors for a stratified model.
- var** the variance-covariance matrix for the parameters, including the `log(scale)` parameter(s).
- loglik** a vector of length 2, containing the log-likelihood for the baseline and full models.
- iter** the number of iterations required
- linear.predictors** the linear predictor for each subject.
- df** the degrees of freedom for the final model. For a penalized model this will be a vector with one element per term.
- scale** the scale factor(s), with length equal to the number of strata.
- idf** degrees of freedom for the initial model.
- means** a vector of the column means of the coefficient matrix.
- dist** the distribution used in the fit.
- weights** included for a weighted fit.

The object will also have the following components found in other model results (some are optional): `linear.predictors`, `weights`, `x`, `y`, `model`, `call`, `terms` and `formula`. See `lm`.

<code>survregDtest</code>	<i>Verify a <code>survreg</code> distribution</i>
---------------------------	---

---

Description

This routine is called by `survreg` to verify that a distribution object is valid.

Usage

```
survregDtest(dlist, verbose = F)
```

Arguments

- `dlist` the list describing a survival distribution
- `verbose` return a simple TRUE/FALSE from the test for validity (the default), or a verbose description of any flaws.

**Details**

If the `survreg` function rejects your user-supplied distribution as invalid, this routine will tell you why it did so.

**Value**

TRUE if the distribution object passes the tests, and either FALSE or a vector of character strings if not.

**Author(s)**

Terry Therneau

**See Also**

**Examples**

```
# An invalid distribution (it should have "init =" on line 2)
# survreg would give an error message
mycauchy <- list(name='Cauchy',
  init<- function(x, weights, ...)
    c(median(x), mad(x)),
  density= function(x, parms) {
    temp <- 1/(1 + x^2)
    cbind(.5 + atan(temp)/pi, .5+ atan(-temp)/pi,
      temp/pi, -2 *x*temp, 2*temp^2*(4*x^2*temp -1))
  },
  quantile= function(p, parms) tan((p-.5)*pi),
  deviance= function(...) stop('deviance residuals not defined')
)

survregDtest(mycauchy, TRUE)
```

---

survSplit

---

*Split a survival data set at specified times*

---

**Description**

Given a survival data set and a set of specified cut times, split each record into multiple subrecords at each cut time. The new data set will be in ‘counting process’ format, with a start time, stop time, and event status for each record.

**Usage**

```
survSplit(data, cut, end, event, start, id = NULL, zero = 0,
  episode=NULL)
```

**Arguments**

data	data frame
cut	vector of timepoints to cut at
end	character string with name of event time variable
event	character string with name of censoring indicator
start	character string with name of start time variable (will be created if it does not exist)
id	character string with name of new id variable to create (optional)
zero	If <code>start</code> doesn't already exist, this is the time that the original records start. May be a vector or single value.
episode	character string with name of new episode variable (optional)

**Details**

The function also works when the original data are in counting-process format, but the `id` and `episode` options are of little use in this context.

**Value**

New, longer, data frame.

**See Also**

[Surv](#), [cut](#), [reshape](#)

**Examples**

```
aml3<-survSplit(aml, cut=c(5,10,50), end="time", start="start",
               event="status", episode="i")

summary(aml)
summary(aml3)

coxph(Surv(time, status)~x, data=aml)
## the same
coxph(Surv(start, time, status)~x, data=aml3)

aml4<-survSplit(aml3, cut=20, end="time", start="start", event="status")
coxph(Surv(start, time, status)~x, data=aml4)
```

---

tcut

---

*Factors for person-year calculations*

---

**Description**

Attaches categories for person-year calculations to a variable without losing the underlying continuous representation

**Usage**

```
tcut(x, breaks, labels, scale=1)
## S3 method for class 'tcut'
levels(x)
```

**Arguments**

x	numeric/date variable
breaks	breaks between categories, which are right-continuous
labels	labels for categories
scale	Multiply x and breaks by this.

**Value**

An object of class `tcut`

**See Also**

[cut](#), [pyears](#)

**Examples**

```
mdy.date <- function(m,d,y)
  as.Date(paste(ifelse(y<100, y+1900, y), m, d, sep='/'))
temp1 <- mdy.date(6,6,36)
temp2 <- mdy.date(6,6,55) # Now compare the results from person-years
#
temp.age <- tcut(temp2-temp1, floor(c(-1, (18:31 * 365.24))),
  labels=c('0-18', paste(18:30, 19:31, sep='-')))
temp.yr <- tcut(temp2, mdy.date(1,1,1954:1965), labels=1954:1964)
temp.time <- 3700 #total days of fu
py1 <- pyears(temp.time ~ temp.age + temp.yr, scale=1) #output in days
py1
```

---

tmerge

*Time based merge for survival data*

---

**Description**

A common task in survival analysis is the creation of start,stop data sets which have multiple intervals for each subject, along with the covariate values that apply over that interval. This function aids in the creation of such data sets.

**Usage**

```
tmerge(data1, data2, id,..., tstart, tstop, options)
```

## Arguments

<code>data1</code>	the primary data set, to which new variables and/or observation will be added
<code>data2</code>	optional second data set in which the other arguments will be found
<code>id</code>	subject identifier
<code>...</code>	operations that add new variables or intervals, see below
<code>tstart</code>	optional variable to define the valid time range for each subject, only used on an initial call
<code>tstop</code>	optional variable to define the valid time range for each subject, only used on an initial call
<code>options</code>	a list of options. Valid ones are <code>id</code> , <code>tstart</code> , and <code>tstop</code> , which will be the names of the three mandatory variables in the output data. The other is <code>defer</code> , which sets a numeric amount of time before an event when covariate changes are disallowed (the are deferred until after the event in that case.)

## Details

The program is usually run in multiple passes, the first of which defines the basic structure, and subsequent ones that add new variables to that structure. For a more complete explanation of how this routine works refer to the vignette on time-dependent variables.

There are 4 types of optional arguments: a time dependent covariate (`tdc`), cumulative count (`cumtdc`), event (`event`) or cumulative event (`cumevent`). Time dependent covariates change their values before an event, events are outcomes.

- `newname = tdc(y, x)` A new time dependent covariate variable will created. The argument `y` is assumed to be on the scale of the start and end time, and each instance describes the occurrence of a "condition" at that time. The second argument `x` is optional. In the case where `x` is missing the count variable starts at 0 for each subject and becomes 1 at the time of the event; if `x` is present the count is set to the value of `x`. If a given subject has multiple rows of data with the same time value the sum of those rows will be assigned.

`newname = cumtdc(y,x)` Similar to `tdc`, except that the event count is accumulated over time for each subject.

`newname = event(y,x)` Mark an event at time `y`. In the usual case that `x` is missing, the new 0/1 variable will be similar to the 0/1 status variable of a survival time, and that is in fact how it will normally be used. For multiple types of endpoints the `x` argument can be used to encode the type of event.

`newname = cumevent(y,x)` Cumulative events.

Say that a subject had an interval of observation from age 17 to 38, denoted as (17, 38] and that a marker occurs at age 24. A `tdc` variable is a predictor which is assumed to apply from the time it occurred to the end of followup for the subject. The updated data set will have intervals of (17,24] and (24, 38] with a count of 0 for the first interval and 1 for the second, assuming no other occurrences for this subject at exactly time 24. An event is an outcome, so if coded as an event the said occurrence would be placed in the (17,24] interval, with the new variable marking that this interval finished with an event.

## Value

a data frame with two extra attributes `tname` and `tcount`. The first contains the names of the key variables; its persistence from call to call allows the user to avoid constantly reentering the `options` arguments. The `tcount` variable contains counts of the match types. New time values

that occur before the first interval for a subject are "early", those after the last interval for a subject are "late", and those that fall into a gap are of type "gap".

The most common type will usually be "within", for those new times that fall inside an existing interval and cause it to be split into two. Observations that fall exactly on the edge of an interval are counted as "leading" edge, "trailing" or "boundary". The first corresponds for instance to an occurrence at 17 for someone with an interval (17, 35] who is not at risk just before time 17. A `tdc` at time 17 will affect this interval but not an `event`. Symmetrically an `event` occurrence at 35 would count in the (17,35] interval, but a `tdc` would not. The last case is where the main data set has touching intervals for a subject, e.g. (17, 28] and (28,35] and a new occurrence lands at the join. Events will go to the earlier interval and counts to the latter one.

It is wise to look at `attr(data, 'tcount')` after each step of a data set build to avoid surprises.

These extra attributes are ephemeral, and will be discarded if the dataframe is modified in any way. This is intentional.

tobin

*Tobin's Tobit data*

---

### Description

Economists fit a parametric censored data model called the 'tobit'. These data are from Tobin's original paper.

**Usage**

```
tobin
```

**Format**

A data frame with 20 observations on the following 3 variables.

**durable** Durable goods purchase

**age** Age in years

**quant** Liquidity ratio (x 1000)

**Source**

J Tobin (1958), Estimation of relationships for limited dependent variables. *Econometrica* **26**, 24–36.

**Examples**

```
tfit <- survreg(Surv(durable, durable>0, type='left') ~age + quant,
               data=tobin, dist='gaussian')

predict(tfit, type="response")
```

---

transplant

*Liver transplant waiting list*

---

**Description**

Subjects on a liver transplant waiting list from 1990-1999, and their disposition: received a transplant, died while waiting, withdrew from the list, or censored.

**Usage**

```
data("transplant")
```

**Format**

A data frame with 815 observations on the following 6 variables.

**age** age at addition to the waiting list

**sex** m or f

**abo** blood type: A, B, AB or O

**year** year in which they entered the waiting list

**futime** time from entry to final disposition

**event** final disposition: censored, death, ltx or withdraw

## Details

This represents the transplant experience in a particular region, over a time period in which liver transplant became much more widely recognized as a viable treatment modality. The number of liver transplants rises over the period, but the number of subjects added to the liver transplant waiting list grew much faster. Important questions addressed by the data are the change in waiting time, who waits, and whether there was an consequent increase in deaths while on the list.

Blood type is an important consideration. Donor livers from subjects with blood type O can be used by patients with A, B, AB or O blood types, whereas a recipient of type B cannot accept an A or AB liver for instance. Thus type O subjects on the waiting list are at a disadvantage, since the pool of competitors is larger for type O donor livers.

This data is of historical interest but has little relevance to current practice. Liver allocation policies have evolved and now depend directly on individual patient's risk and need, assessments of which are regularly updated while a patient is on the waiting list. The overall organ shortage remains acute, however.

## Examples

```
period <- cut(transplant$year, c(1989, 1992, 1995, 1997, 2000),
              labels=c('90-92', '93-95', '96-97', '98-99'))
pfit <- survfit(Surv(futime, event) ~ period, transplant)
pfit[,2] #time to liver transplant
plot(pfit[,2], mark.time=FALSE, col=1:4, lwd=2, xmax=735,
      xscale=30.5, xlab="Months", ylab="Fraction transplanted",
      xaxt = 'n')
temp <- c(0, 6, 12, 18, 24)
axis(1, temp, temp)

untangle.specials    *Help Process the 'specials' Argument of the 'terms' Function.*

---

## Description

Given a `terms` structure and a desired special name, this returns an index appropriate for subscripting the `terms` structure and another appropriate for the data frame.

## Usage

```
untangle.specials(tt, special, order=1)
```

## Arguments

<code>tt</code>	a <code>terms</code> object.
<code>special</code>	the name of a special function, presumably used in the <code>terms</code> object.
<code>order</code>	the order of the desired terms. If set to 2, interactions with the special function will be included.

**Value**

- a list with two components:
- vars                    a vector of variable names, as would be found in the data frame, of the specials.
  - terms                  a numeric vector, suitable for subscripting the terms structure, that indexes the terms in the expanded model formula which involve the special.

**Examples**

```
formula<-Surv(tt,ss)~x+z*strata(id)
tms<-terms(formula,specials="strata")
## the specials attribute
attr(tms,"specials")
## main effects
untangle.specials(tms,"strata")
## and interactions
untangle.specials(tms,"strata",order=1:2)
```

uspop2	<i>Projected US Population</i>
--------	--------------------------------

---

**Description**

US population by age and sex, for 2000 through 2020

**Usage**

```
data(uspop2)
```

**Format**

The data is a matrix with dimensions age, sex, and calendar year. Age goes from 0 through 100, where the value for age 100 is the total for all ages of 100 or greater.

**Details**

This data is often used as a "standardized" population for epidemiolgy studies.

**Source**

NP2008\_D1: Projected Population by Single Year of Age, Sex, Race, and Hispanic Origin for the United States: July 1, 2000 to July 1, 2050, [www.census.gov/population/projections](http://www.census.gov/population/projections).

[uspop](#)

Examples

```
us50 <- uspop2[51:101,, "2000"] #US 2000 population, 50 and over
age <- as.integer(dimnames(us50)[[1]])
smat <- model.matrix( ~ factor(floor(age/5)) -1)
ustot <- t(smat) %*% us50 #totals by 5 year age groups
temp <- c(50,55, 60, 65, 70, 75, 80, 85, 90, 95)
dimnames(ustot) <- list(c(paste(temp, temp+4, sep="-"), "100+"),
                        c("male", "female"))
```

---

veteran	<i>Veterans' Administration Lung Cancer study</i>
---------	---

---

Description

Randomised trial of two treatment regimens for lung cancer. This is a standard survival analysis data set.

Usage

```
veteran
```

Format

- trt: 1=standard 2=test
- celltype: 1=squamous, 2=smallcell, 3=adeno, 4=large
- time: survival time
- status: censoring status
- karno: Karnofsky performance score (100=good)
- diagtime: months from diagnosis to randomisation
- age: in years
- prior: prior therapy 0=no, 1=yes
